RESUMEN

En éste trabajo se presenta los diseños y procedimientos operativos para la perforación de pozos horizontales como una alternativa de explotación de campos maduros de baja productividad.

La realización del trabajo obedece a que el Activo de Producción Cinco Presidentes realizó un estudio geológico del campo Rodador teniendo como resultado un incremento en la reserva original de aceite del 75%. Considerando que el campo es de desarrollo y se cuenca con suficiente información para cimentación, se propone la perforación de 4 pozos horizontales para incrementar la producción de aceite en un 96% con relación a su producción actual.

Aquí se desarrolla solamente el diseño de uno de los pozos horizontales, en virtud de que los cuatro pozos serán perforados desde la macropera del pozo Rodador 83 y con esto explotar las diferentes arenas productoras del campo.

Considerando que en nuestro país apenas se han perforado 22 pozos de los 20,000 perforados en todo el mundo, se presentan las diferentes condiciones operativas que pudieran influir en el éxito de la perforación de los pozos, siendo el torque y el arrastre los mas importantes

Finalmente, se proponen las diferentes sartas y características de los fluidos de perforación que se proponen para la perforación de los pozos horizontales, así como algunas recomendaciones operativas durante las diferentes actividades de la perforación, como son: viajando, perforando rotado y perforando sin rotación.

INTRODUCCION

Ha caido en desuso el objetivo de la perforación únicamente como la comunicación del yacimiento con la superficie, atravesando de manera perpendicular la formación productora. Ahora, es más ambicioso, se buscan en algunos pozos trayectorias paralelas al eje de las capas del yacimiento, para ello se requiere la perforación de trayectorias altamente desviadas y horizontales.

El perforar pozos horizontales ha demostrado que incrementan los ritmos de producción en campos existentes, donde los pozos verticales son de bajo índice de productividad, tanto que la perforación horizontal puede considerarse como un medio de recuperación secundaria.

Los pozos horizontales incrementan drásticamente el área de drenaje y su eficiencia por gravedad. Esta técnica se puede emplear tanto en formaciones de areniscas como en formaciones de calizas.

La planeación y desarrollo de proyectos para perforar yacimientos con pozos horizontales, requieren de la integración de grupos multidisciplinarios, formados por ingenieros petroleros, geólogos, petrofísicos y expertos de las compañías de servicios. Se debe de contemplar todos los planteamientos necesarios, no solo en el diseño de la perforación y terminación, sino también los requerimientos de la etapa direccional y horizontal.

A nivel mundial se han perforado alrededor de 20,000 pozos horizontales, de los cuales 22 pozos apenas se han perforado en México en los campos petroleros de Agua Fría, Cuitlahuac, Franco Española, Poza Rica, Cerro Azul, Santa Agueda, Akal, Abkatún, Zapp, Cerro Nanchital y Catedral.

El presente trabajo tiene como objetivo proponer la perforación horizontal del pozo Rodador 504, en el campo del mismo nombre perteneciente al Activo de producción Cinco Presidentes, en la Región Sur.

Este pozo forma parte de cuatro pozos horizontales programados para ser perforados con la finalidad de incrementar la producción de aceite del campo en un 96%. La arena a ser explotada por el pozo es la 21 a una profundidad vertical de 3050 m.

CAPITULO I.- CONCEPTOS BÁSICOS DE PERFORACIÓN HORIZONTAL.

Definición de Perforación Horizontal.

Se define a un pozo horizontal aquel donde la última etapa del pozo que se perfora es horizontal o paralela al yacimiento (pozos de gran desviación).

Los pozos horizontales pueden ser utilizados para incrementar los ritmos de producción en campos existentes, debido a que se aumenta el área de drenaje y su eficiencia por gravedad. La perforación horizontal permite desarrollar campos costafuera con pocos pozos y por ende con plataformas más pequeñas y económicas que las convencionales.

La perforación horizontal se puede aplicar a yacimientos de baja permeabilidad, a yacimientos cuyos fluidos son de alta viscosidad, a yacimientos naturalmente fracturados conectando las fracturas con el pozo permitiendo el flujo de los fluidos del yacimiento.

La decisión de desarrollar un yacimiento con pozos horizontales o con pozos verticales, es una decisión que debe tomarse de acuerdo a las características del yacimiento, de las características de los fluidos del yacimiento y esencialmente esa decisión recae en el ámbito de competencia de los geólogos.

Tipos de Pozos Horizontales.

Existen 3 tipos de pozos horizontales que se pueden perforar dependiendo del rango de incremento de ángulo que se utilice para llevar el pozo de la vertical a la horizontal (figura I.1), estos son:

| | |
|----------------|------------------|
| De radio largo | 2° a 6° /100 ft |
| De radio medio | 6° a 20° /100 ft |
| De radio Corto | 1.5° a 3° / ft |

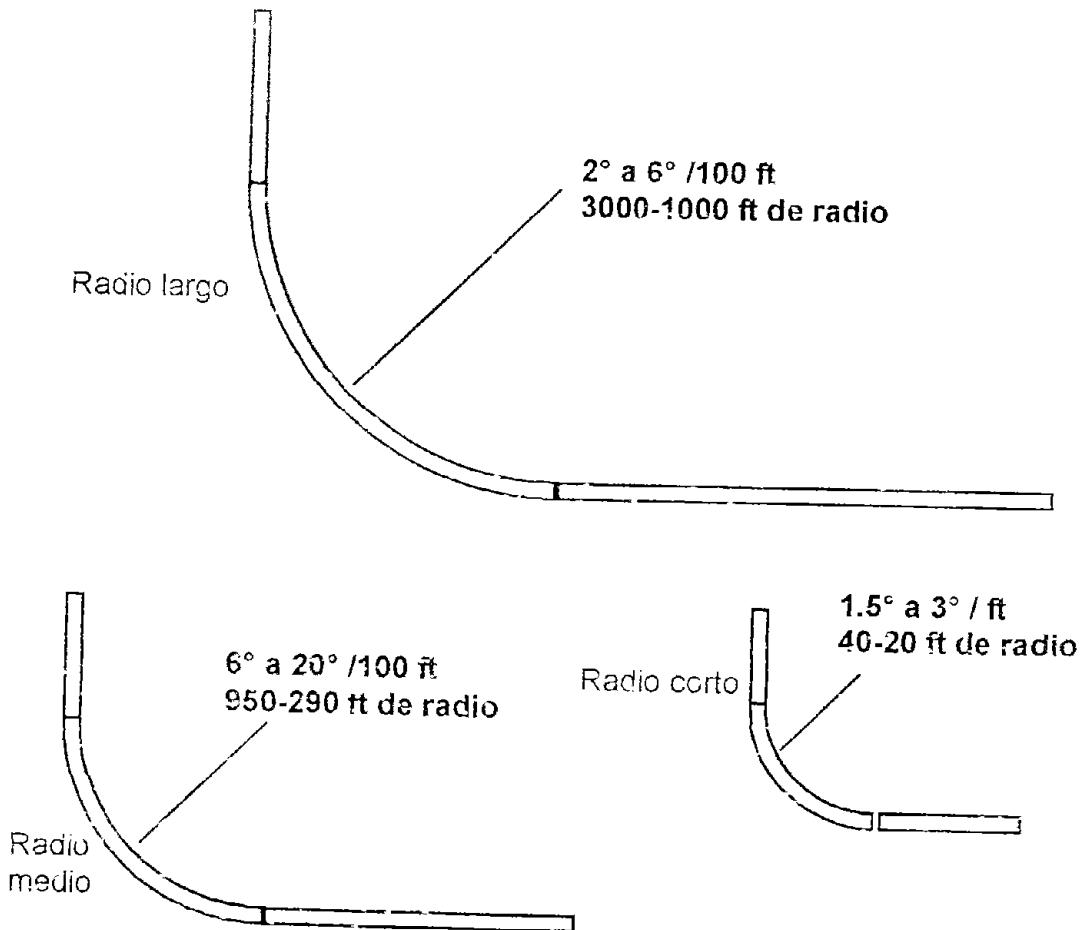

FIGURA I.1
Tipos de pozos horizontales

Curva para llegar de la Vertical a la Horizontal en un Pozo Horizontal.

a) Curva Uniforme.

La curva inicia la desviación con un determinado rango de incremento de ángulo (RIA) y se deja que continúe con dicho RIA hasta que la inclinación final se obtiene (figura I.2).

b) Curva Uniforme.

Después de establecer un RIA programado, una sección tangencial (recta) con la longitud adecuada se perfora usualmente con una inclinación de 45 a 60° para

finalmente ajustar el RIA requerido para llegar a la profundidad total establecida (figura I.3).

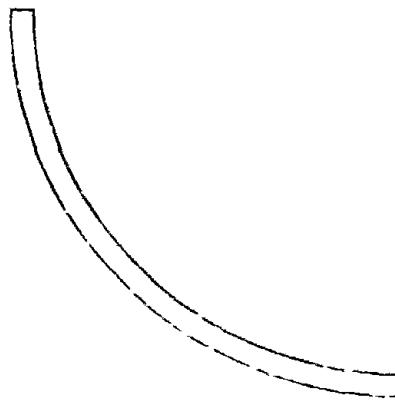

FIGURA I.2
CURVA UNIFORME

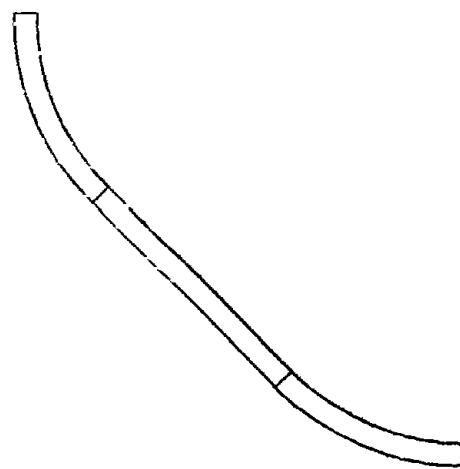

FIGURA I.3
CURVA UNIFORME CON TANGENTE.

Programa de Tuberías de Revestimiento.

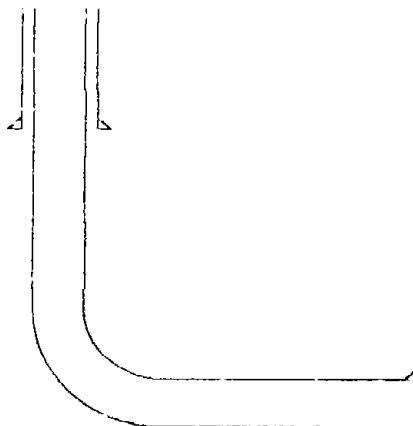

Para el diseño de tuberías de revestimiento se deben de considerar algunos factores que pueden ser determinantes para su asentamiento antes o después del punto de inicio de desviación (KOP), ejemplo de lo anterior son:

- » Zonas de pérdidas de circulación

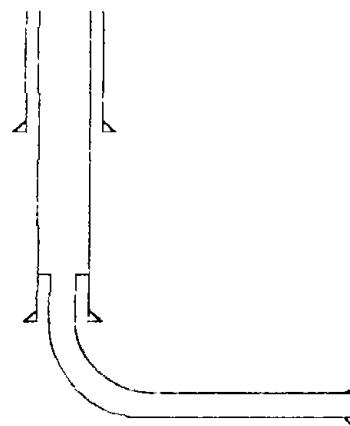

- »Condiciones de derrumbes en el agujero.
- »Zonas de sal plástica.
- »Zonas sobre-presionadas o sub-presionadas.

Las circunstancias específicas del lugar determinarán que tipo de perfil de tuberías de revestimiento se utilizarán. Un programa de tuberías de revestimiento seleccionado para minimizar los costos de perforación sin considerar el costo de la terminación horizontal puede en última instancia reducir el aspecto económico del proyecto al incrementar el costo total del pozo.

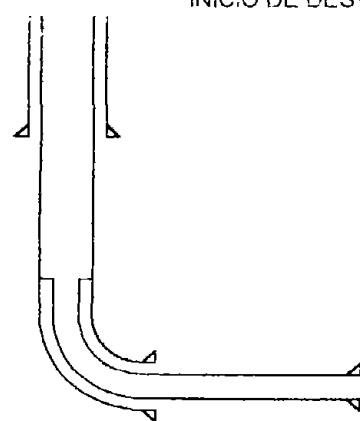

En la figura I.4 se muestran tres perfiles de tuberías de revestimiento básicos en pozos horizontales.

Torqué y Arrastre en Perforación Horizontal.

La reducción y control de troqué y arrastre es un objetivo muy importante en el diseño de un pozo horizontal. La presencia de torque y arrastre no puede eliminarse, pero si se ignora, la eficiencia en la perforación se reducirá y el objetivo final del pozo puede no alcanzarse económicamente. La importancia del monitoreo del torque y el arrastre no puede ser subestimada. El monitoreo puede usarse para predecir el inicio de problemas de limpieza del agujero y pegaduras de tubería.

a) Torque.

El torque es la torsión que resulta de la fuerza lateral de contacto de la sarta de perforación con la pared del pozo que se opone a la rotación de dicha sarta.

Para el torque se toman las siguientes consideraciones:

- 1.- La trayectoria curva del pozo puede representarse por un arco.
- 2.- El agujero lateral es aproximado a la horizontal.
- 3.- La tubería en la sección horizontal no está pandeada.

El torque se puede calcularse por:

$$T = \frac{F_c * D_{jt} * F_C}{24}$$

Donde :

F_c = Torque (lb - pie)

D_{jt} = Diametro de la junta (pulg.)

F_f = Factor de Fricción (adim.)

F_C = Fuerza lateral de contacto (lbs)

La Fuerza lateral de contacto en una sección horizontal será igual a:

$$F_c = W_s$$

Donde :

W_s = Peso flotado de los elementos tubulares en la sección horizontal (lbs)

La Fuerza lateral de contacto en una sección recta inclinada será igual a:

$$F_C = W_s * \operatorname{sen} \theta$$

Donde:

W_s = Peso de la tubería en el lodo en la sección inclinada (lbs.)

θ = Ángulo de inclinación (grados)

La Fuerza lateral de contacto en una sección curva será aproximadamente igual a:

$$F_C = W_s * \operatorname{sen} \left(\frac{\theta_1 + \theta_2}{2} \right)$$

Donde:

W_s = Peso flotado de la tubería en la sección de la curva (lbs)

θ_1 = Ángulo inicial de la curva (grados)

θ_2 = Ángulo final de la curva (grados)

Los parámetros involucrados en la mecánica del torque de la sarta de perforación se muestra en la figura I.5.

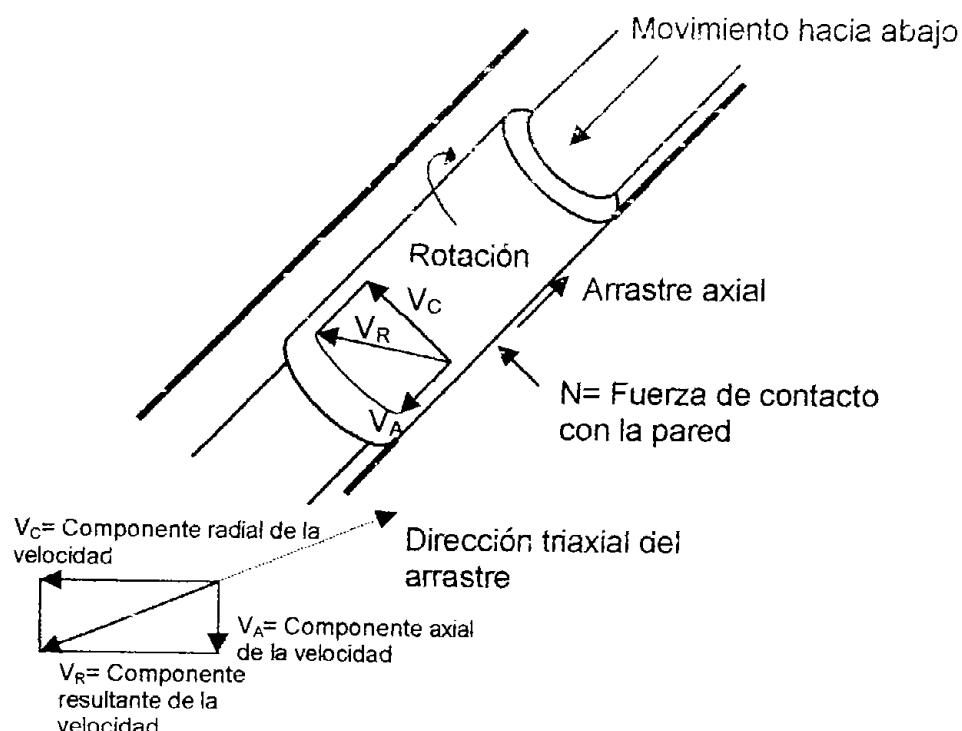

FIGURA I.5 Mecánica del Torque

La fórmula para calcular la fuerza lateral de contacto en la sección curva es aproximada y considera una recta con una inclinación igual al promedio de los ángulos inicial y final de la curva.

Una solución mucho más exacta será fragmentar dicha curva en muchas secciones rectas lo suficiente para que la diferencia entre lo real y lo calculado sea marginal. La fuerza lateral de contacto será:

$$Fc_1 = W_s * \operatorname{sen}\left(\frac{\theta_1 + \theta_2}{2}\right)$$

$$Fc_2 = \frac{W_s}{2} * \operatorname{sen}\left(\frac{\theta_1 + \theta_2}{2}\right) + \frac{W_s}{2} * \operatorname{sen}\left(\frac{\theta_2 + \theta_3}{2}\right)$$

$$Fc_i = \frac{W_s}{i} * \operatorname{sen}\left(\frac{\theta_1 + \theta_2}{2}\right) + \dots + \frac{W_s}{i} * \operatorname{sen}\left(\frac{\theta_{i-1} + \theta_i}{2}\right)$$

Donde .

i = Número de secciones en que se fracciona la curva

b) Arrastre.

El arrastre en el agujero es el resultado del contacto entre la sarta de perforación y la pared del pozo. En su forma más simple, la fuerza de fricción de deslizamiento (F) es el producto del factor de fricción (ff) y la fuerza que actúa normalmente a la superficie de contacto (N).

En un agujero vertical con mínima desviación, la fricción por deslizamiento o arrastre es despreciable debido a la ausencia de fuerzas normales activas. En un agujero inclinado o agujeros con severidades grandes, las fuerzas normales actuantes en la pared de la tubería dan como resultado un arrastre o fricción de deslizamiento entre agujero y la sarta de perforación.

Se observaran fuerzas de fricción por deslizamiento en forma de torque en la sarta de perforación (debido a la rotación), fuerza de arrastre (debido al deslizamiento o movimiento axial de la sarta) o una combinación de ambas.

Si la sarta de perforación se saca sin rotación, las fuerzas de fricción se verán como arrastre. Si la tubería únicamente es rotada las fuerzas de fricción se

observarán como torque. Las fuerzas de fricción por deslizamiento se oponen al movimiento y por lo tanto la fuerza de fricción actúa en un sentido opuesto al vector velocidad. La figura I.5 muestra las componentes del vector velocidad debido a la rotación de la tubería (V_c) y el movimiento hacia abajo (V_a). El vector de velocidad total (V_r) se calcula fácilmente, el arrastre por fricción ocurre a lo largo del vector (V_r) pero en el sentido opuesto. Los componentes de arrastre torsional y axial son directamente proporcionales a sus respectivas contrapartes de velocidad.

Cuando la tubería de perforación es rotada y reciproquedada el torque y el arrastre variarán dependiendo de la velocidad rotacional y axial de la tubería. Los beneficios de rotar se pueden observar en la sección lateral del agujero cuando el rango de penetración puede hasta duplicarse cuando se inicia a perforar rotando la tubería después de haber perforado sin rotación. El arrastre el cual reduce significativamente el peso aplicado sobre la barrena se supera incrementando el torque, por medio de iniciar a rotar la tubería.

Las fuerzas de fricción por deslizamiento se observan en forma de torque o arrastre dependiendo del tipo de movimiento de la tubería, aunque la fuente de dichas fuerzas de fricción son las mismas para ambos torque y arrastre.

Una sarta de perforación que actúa en una pateperro, crea una fuerza lateral en el interior del pateperro cuando la tubería pega con la pared (Figura I.6). Esta fuerza lateral actuando en la superficie de contacto genera una fuerza de fricción que actúa paralela a la dirección del movimiento de la sarta de perforación. Si la tubería se saca del agujero, la fuerza de fricción será paralela al eje de la tubería y se observa como arrastre o incremento en el peso al gancho. La fuerza de fricción esta relacionada con la tensión de la tubería debajo del pateperro y severidad del mismo.

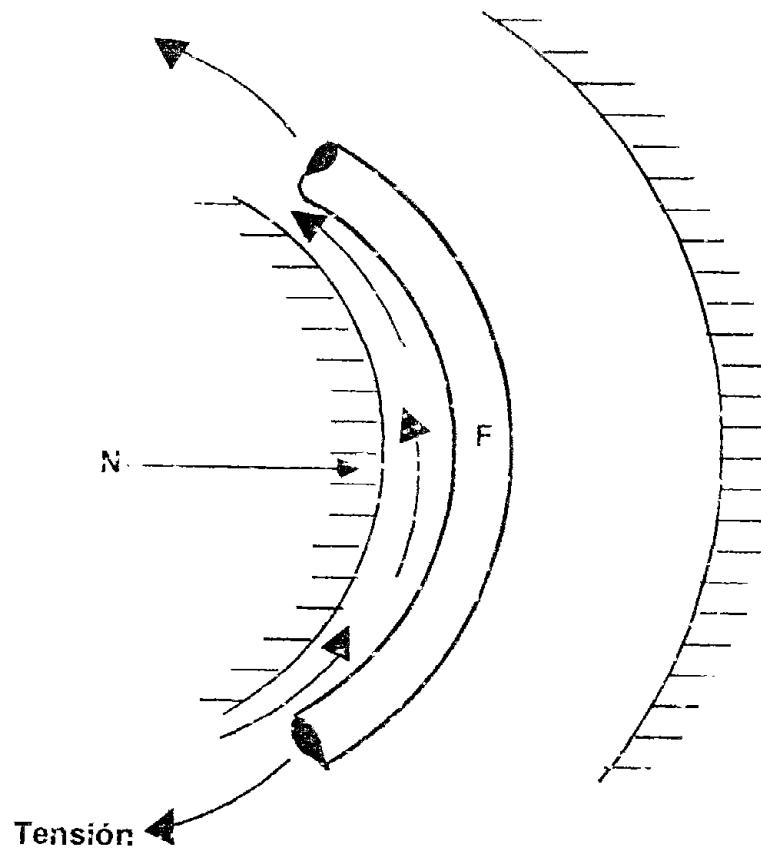

FIGURA I.6
Mecánica del Arrastre

El arrastre en un agujero inclinado depende del peso de la sarta (W_s) y la inclinación del agujero. Únicamente la componente que actúa normalmente a la pared del agujero contribuye a la fuerza de fricción. La componente que actúa axialmente a la sarta contribuye a la compresión de la sarta. La combinación de estas 2 fuerzas de fricción por deslizamiento contribuyen significativamente al torque y arrastre experimentados en los pozos horizontales.

El torque y arrastre resultante del ensamblaje del fondo de pozo es normalmente despreciable y constante si la limpieza del agujero no es un problema. El arrastre del ensamblaje de fondo de pozo es máximo cuando el motor direccional se corre en la parte recta.

La barrena, los estabilizadores y los perfiles del diámetro exterior de los elementos tubulares actuando sobre salientes y camas de recortes pueden contribuir significativamente al arrastre, este tipo de arrastre no es fácil de calcular. Esas fuerzas frecuentemente son las responsables de pégaduras de sarta. El reconocimiento de problemas inminentes es difícil a menos que el arrastre debido a pateperro y al peso de la sarta sean monitoreados.

Los modelos de computación para calcular arrastre y torque son útiles en la fase de diseño y en la fase de perforación de agujeros con elevada inclinación. El utilizar un modelo de computación para reconocer el surgimiento de un problema en el agujero mientras se perfora es importante.

Los valores observados de torque y arrastre en el agujero se utilizan como datos para determinar los valores de los factores de fricción. Un factor de fricción que se incrementa puede indicar el inicio de un problema en el agujero.

Los modelos de torque y arrastre requieren un reporte completo de la geometría de la sarta de perforación y del pozo, lo cual incluye mediciones de toda la longitud del pozo. Estos programas pueden calcular las fuerzas de torque y arrastre directamente si se le considera como dato el factor de fricción. Si lo que se desea es el factor de fricción como respuesta, el torque y arrastre observado en el pozo se ponen como datos y el factor de fricción es obtenido por métodos interactivos para concordar con los datos introducidos.

El diseño de torque y arrastre en pozos horizontales se elabora en tres secciones: el agujero vertical, el agujero de incremento de ángulo y el agujero horizontal.

El agujero vertical hasta el punto de inicio de desviación se trata como un agujero de pozo convencional. Si el pozo no está desviado, el arrastre será el resultado de pequeños pateperro y la tensión de la sarta de perforación. Para propósito de programación, se utilizan los datos de arrastre de un pozo vecino asimilares el área.

La sección de incremento de ángulo del punto de inicio de desviación hasta el final de la curva es influenciado por el arrastre de la severidad y el arrastre del agujero inclinado. El arrastre en esta sección del agujero es menor en un pozo de radio medio que un pozo de radio largo. Maximizando el rango de incremento de ángulo,

la severidad aumenta pero la longitud del agujero curvo disminuye. Esto reduce el peso de los elementos tubulares en la sección de incremento de ángulo y minimiza la tensión debajo del punto de inicio de desviación.

El arrastre en la sección horizontal es dominado por el peso de la sarta de perforación y el arrastre del ensamble de fondo de pozo, las severidades en el agujero horizontal no contribuyen de manera significativa al arrastre debido a que la tubería descansa en la parte baja del agujero y la tensión en la tubería baja.

Para propósito de diseño el arrastre en un pozo horizontal puede calcularse de manera aproximada usando la siguiente ecuación:

$$F = F_f * F_c$$

Donde :

F = Fuerza de fricción por deslizamiento (arrastre), (lbs)

F_f = Factor de fricción (0.2 a 0.4)

F_c = Fuerza lateral de contacto (lbs)

La Fuerza lateral de contacto en una sección horizontal será igual a:

$$Fc = W_s$$

Donde :

W_s = Peso flotado de los elementos tubulares en la sección horizontal (lbs)

La Fuerza lateral de contacto en una sección recta inclinada será igual a:

$$Fc = W_s * \operatorname{sen}\theta$$

Donde :

W_s = Peso de la tubería en el lodo en la sección inclinada (lbs.)

θ = Ángulo de inclinación (grados)

La Fuerza lateral de contacto en una sección curva será aproximadamente igual a:

$$Fc = W_s * \operatorname{sen}\left(\frac{\theta_1 + \theta_2}{2}\right)$$

Donde:

W_s = Peso flotado de la tubería en la sección de la curva (lbs)

θ_1 = Ángulo inicial de la curva (grados)

θ_2 = Ángulo final de la curva (grados)

Al igual que en caso de la fórmula para calcular el torque, la fórmula en la sección curva es aproximada y podrá calcularse de manera casi exacta con el mismo método interactivo.

El minimizar el peso del ensamble de fondo de pozo es una alternativa para reducir el arrastre permanente. La reducción en el factor de fricción reducirá el arrastre pero ésta reducción puede perderse si se desarrollan problemas de limpieza del agujero. El diseño de arrastre deberá efectuarse con el máximo factor de fricción esperado.

En la figura 1.7 se muestra el efecto de las camas de recorte en el ensamble de fondo. El peor caso será cuando el ensamble de fondo se pega. Si el ensamble se pega cuando se jala para sacar la barrena del agujero, se puede entonces martillar la sarta hacia abajo para liberarla.

El monitoreo del torque y arrastre puede ser una valiosa herramienta para percatarse del desarrollo de camas de recortes. El desarrollo de camas de recortes normalmente elevan el factor de fricción, esto incrementa el torque y arrastre en el agujero.

Los factores de fricción se han determinado usando modelos de computadora y metiendo como datos los valores reales de torque y arrastre monitoreados en pozos horizontales. Esta aproximación global concuerda con los resultados de investigaciones y da como factores de fricción de 0.2 a 0.4 para la mayoría de los sistemas de lodo. Los factores que influyen al factor de fricción, incluyen tipo de lodo, litología de la formación, configuración de las juntas y programa de tuberías de revestimiento.

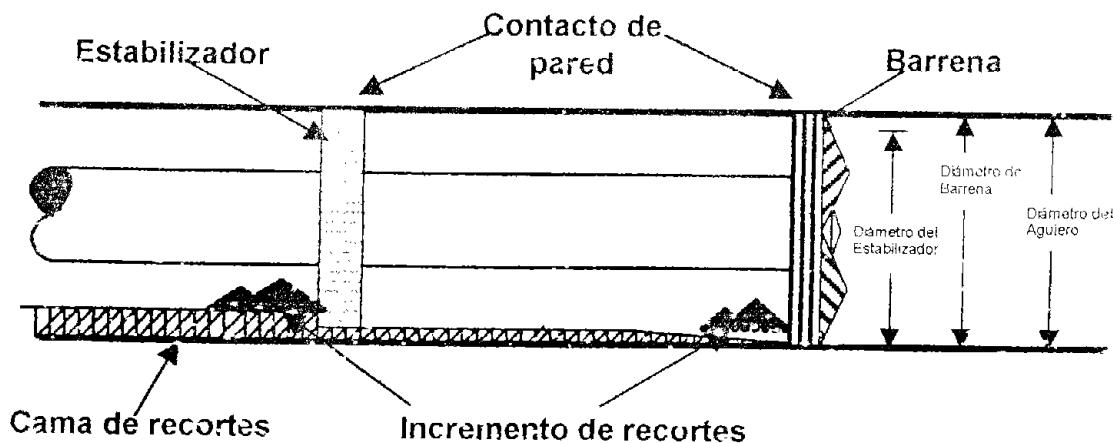

FIGURA I.7
Acumulación de Recortes

c) Fatiga.

Para optimizar la perforación de pozos horizontales especialmente si exceden de un RIA de $20^\circ/100\text{pie}$ se deben considerar los esfuerzos adicionales que impactan el funcionamiento de los aparejos, así como la fatiga.

En la perforación de pozos horizontales los cuatro factores determinantes en la fatiga de la tubería son:

1. Las cargas de tensión en la tubería que está en la curva.
2. La severidad de la curva.
3. El número de ciclos rotacionales experimentados en la curva.
4. Las propiedades mecánicas de la tubería.

La carga por tensión de la tubería debajo del punto de inicio de desviación (KOP) tienden a ser menor que en el resto del agujero direccional. La razón de esto es que la inclinación a 90° del pozo se construye inmediatamente debajo del KOP y una rápida construcción del ángulo dará una menor longitud disponible debajo del KOP para suspender la carga de tensión de la sarta mientras se perfora.

CAPITULO II.- ANTECEDENTES DEL CAMPO RODADOR.

Ubicación del Campo Rodador

El campo Rodador se localiza en el ejido "Leyes de Reforma", municipio de Cardenas en el estado de Tabasco en la figura II.1 muestra el plano de localización del campo.

FIGURA II.1
Plano de Localización del
Campo Rodador

Datos Generales.

El campo Rodador cuenta con una superficie de 4,843 Km², el yacimiento pertenece a la formación Encanto, época del Mioceno del terciario, tiene 21 arenas con hidrocarburos. La explotación del campo inicio en Junio de 1971.

El campo actualmente tiene 47 pozos perforados de los cuales 11 son productores, con una producción promedio de 227 BPD por pozo.

El campo tiene una reserva remanente de aceite de **31.5 MMBLS**.

Actualmente se tiene una producción acumulada de aceite de **19.837093 MMBLS** y una producción acumulada de gas de **28.030 MMMPC**.

Cuenta con una producción promedio diaria de aceite y gas de **2500 BPD y 2.594 MMPCD**, respectivamente.

El yacimiento es bajo saturado, el aceite es negro con una densidad de 30° a 33° API, las formaciones productoras tienen un espesor que varia de 2 a 40 metros, con una permeabilidad de 5 a 50 md y porosidad de 18 a 22 %.

Actualmente el campo tiene la mejor relación de productividad por pozo en yacimiento arenosos del activo.

El perforar los 4 pozos horizontales programados tiene como objetivo principal incrementar la producción de aceite del campo en un 96%, lo que significaría un incremento de 2400 BPD.

Los pozos están programados para ser perforados desde una macroopera (pozo Rodador 83). Disminuyendo de esta forma el impacto ambiental y aprovechando al máximo la infraestructura existente.

Los pozos a perforar son los siguientes:

Rodador 501

Rodador 503

Rodador 504

Rodador 505

Las formaciones a perforar son las arenas 17, 17-A, 18 y 21

Pronostico de Producción.

En la figura II.9 se presenta una grafica del pronostico de producción tomando en cuenta los cuatro pozos horizontales y dos reentradas en los pozos Rodador 65 y 298.

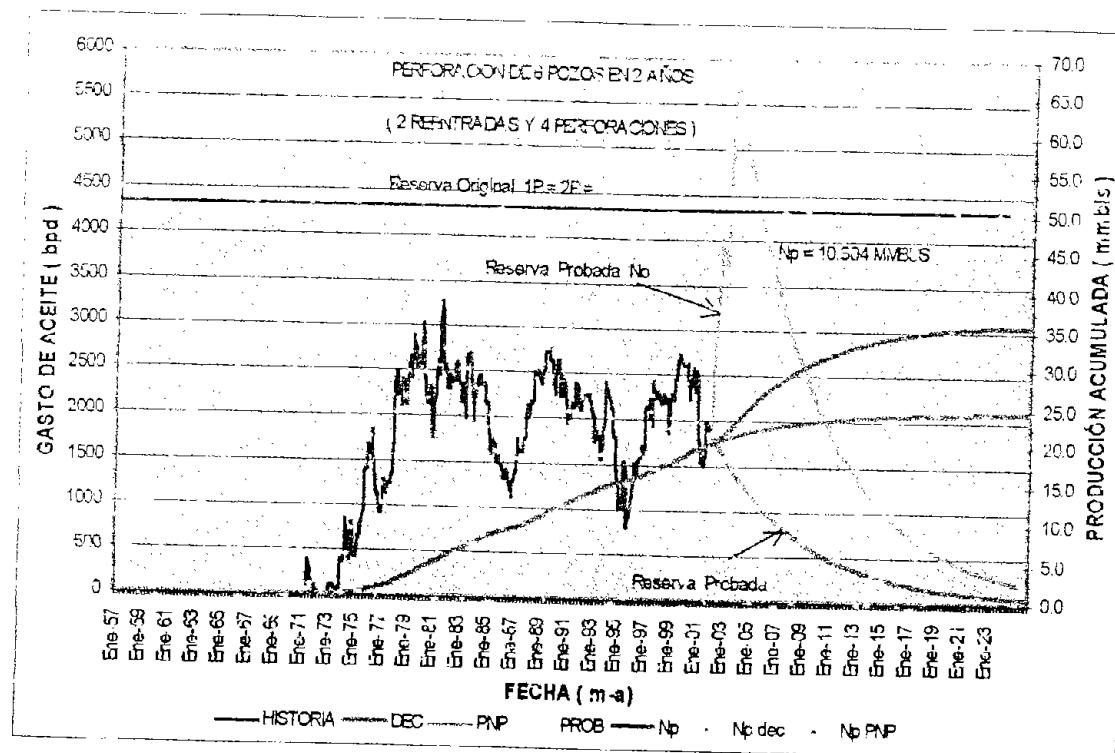

FIGURA II.9
Pronostico de Producción

CAPITULO III.- DISEÑO DE TRAYECTORIA.

En el presente capítulo se analiza la trayectoria de uno de los cuatro pozos horizontales programados debido a que los cuatro pozos serán perforados desde la macroperra del pozo Rodador 83, el cual se tomará como pozo de correlación para el asentamiento de tuberías de revestimiento y fluidos de perforación ya que atraviesa las mismas formaciones que el pozo a perforar. El pozo que se analizará será el Rodador 504, programado para perforarse a 3050 m verticales, hasta la Arena 21.

RESUMEN DE LA PERFORACIÓN DEL POZO RODADOR 83.

La perforación inicio el 23 de enero de 1977, con barrena de 28" perforó a 23.0 m, metió y cementó conductor de 24" a 23m.

Con barrena de 17 1/2" a 20 m, rebajó cemento y perforó a 205 m, con fluido de 1.14 gr/cm³ x 60 seg. Metió TR 13 3/8", J-55, 54.5 lb/pie a 205 m, cementó misma con 25 ton. de cemento tipo "G" alcanzando presión final de 70 kg/cm².

Con barrena 12 1/4" a 194 m, checó cima de cemento, poco TR 13 3/8" con 105 kg/cm² satisfactoriamente, rebajó accesorios y perforó con fluido de 1.22 gr/cm³ x 55 seg a 1705 m. Metió TR 9 5/8" combinada quedando: 304 m de N-80, 40 lb/pie, 306 m de J-55, 40 lb/pie y 1090 m de J-55, 36 lb/pie, se equipó con zapata guía y cople diferencial. Cemento TR con 30 ton. De cemento tipo "G", alcanzando presión final de 140 kg/cm².

Con barrena 8 1/2" a 1690 m tocó tapón y probó TR 9 5/8" con 70 kg/cm² satisfactoriamente. Rebajó accesorios y perforó hasta 3525m. Se utilizó fluido de control de 1.22 a 1.43 gr/cm³ x 55 seg. Metió TR 6 5/8" combinada a 3374 m, observando pegadura, cementó TR con circulación parcial con 16.5 ton de cemento tipo "G" con aditivos para flujo turbulento y retardador, alcanzando presión final de 210 kg/cm².

Al estar metiendo la TR 6 5/8", se presentó pérdida de circulación a 2875 m. La perforación terminó el 11 de marzo de 1977, el tiempo total de perforación fue de 48 días.

La figura III.1 muestra el estado mecánico del pozo actual, así como también todos los datos del mismo.

Estado Mecánico Rodador 83.

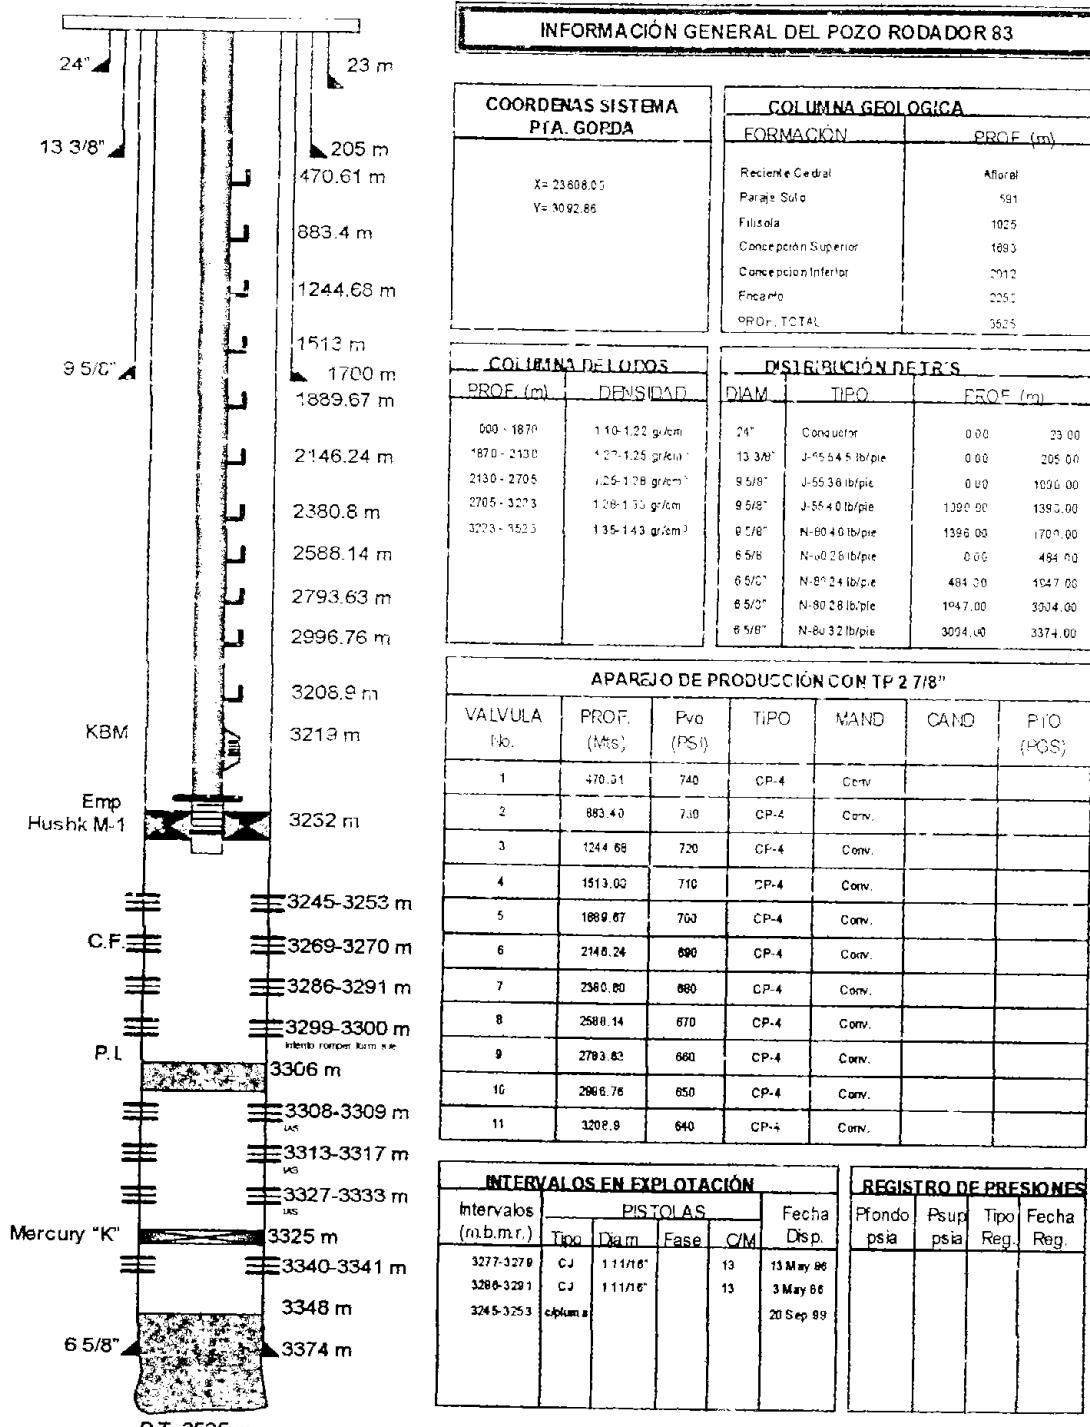

FIGURA III.1
Estado Mecánico Rodador 83

Perfil del Pozo.

Cuando el campo esta perfectamente caracterizado, las practicas de perforación y producción dictan la profundidad de asentamientos de TR's por lo que se puede realizar el asentamiento en función de los pozos de correlación del área. En la figura III.2 se muestra el perfil de resistividades y geopresiones del pozo Rodador 83.

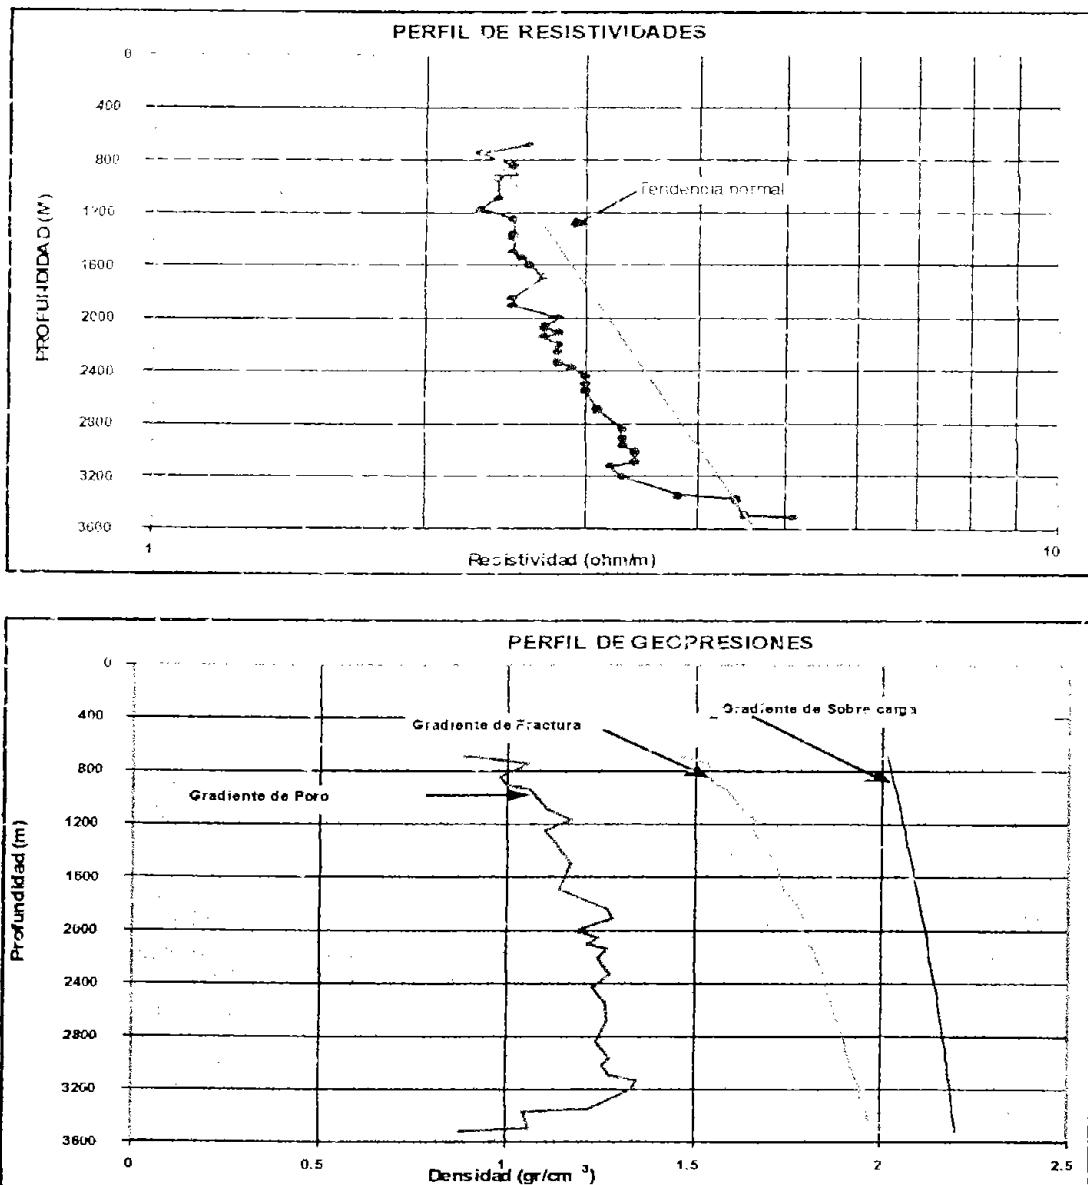

FIGURA III.2
Perfil de Resistividades y Geopresiones,
Rodador 83

Asentamiento de TR'S

De acuerdo al perfil de Resistividades y a las geopresiones del pozo Rodador 83 en la figura III.3 se muestran los asentamientos de las tuberías de revestimiento, así como las densidades de los fluidos de perforación para cada una de las etapas del pozo programado.

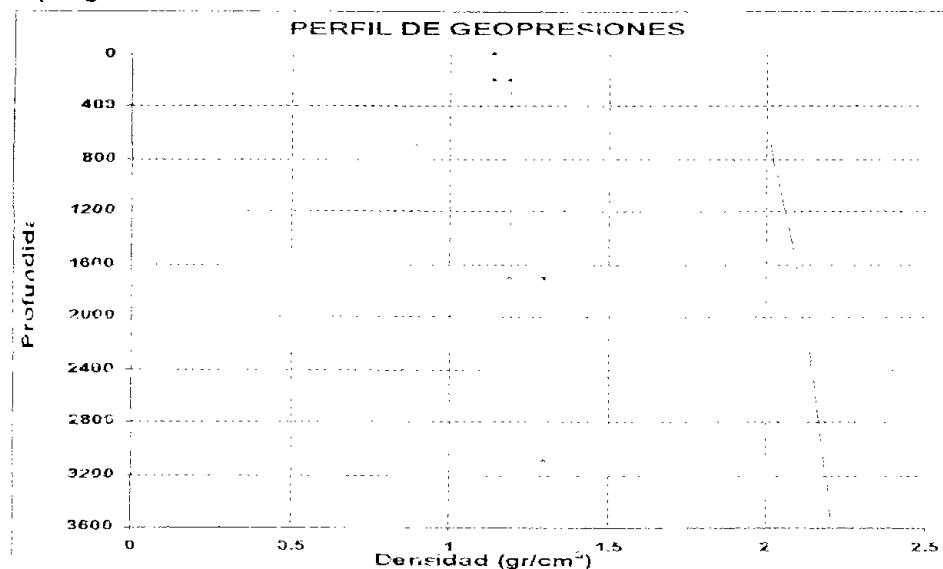

FIGURA III.3
Perfil de Densidades y Asentamiento de TR's

En la Tabla 3.1 se muestra la distribución de las tuberías de revestimiento.

Tabla 3.1

| DISTRIBUCION DE TUBERIAS DE REVESTIMIENTO | | | | | | |
|---|--------------------|------------------------|-------|---------------|----------------|-----------------|
| Diametro de Barrena (pg) | Casing | Diametro Exterior (pg) | Grado | Peso (lb/pie) | Prof. (m) | Fluido (gr/cm³) |
| 28 | Conductor | 24 | | | 0.00 23.00 | 1.14 |
| 17 1/2 | Superficial | 13 3/8 | J-55 | 54.50 | 0.00 205.00 | 1.14 |

| | | 7 | C-95 | 26 | 1500.00 3221.2 | |
| 5 7/8" | Corta (horizontal) | 5 | P-110 | 18 | 3200 3721.2 | 1.3 |

Calculo de la Trayectoria

La trayectoria del pozo se calculó utilizando el método de curvatura mínima e incrementando ángulo hasta llegar a 90° , se consideró un radio de curva de 300 m. El ritmo de incremento se calcula como sigue:

$$q = \frac{180}{\pi} * \frac{30}{R} = \frac{180}{3.1416} * \frac{30}{300} = 5.73^\circ / 30 \text{ mts.}$$

La longitud de la curva se calcula como sigue:

$$L = \frac{90^\circ}{q} = \frac{90 * 30}{5.73} = 471.2 \text{ mts}$$

En la Tabla 3.2 se presentan los cálculos de la trayectoria del pozo.

En la figura III.4 muestra el desplazamiento horizontal del pozo, con una dirección al este franco.

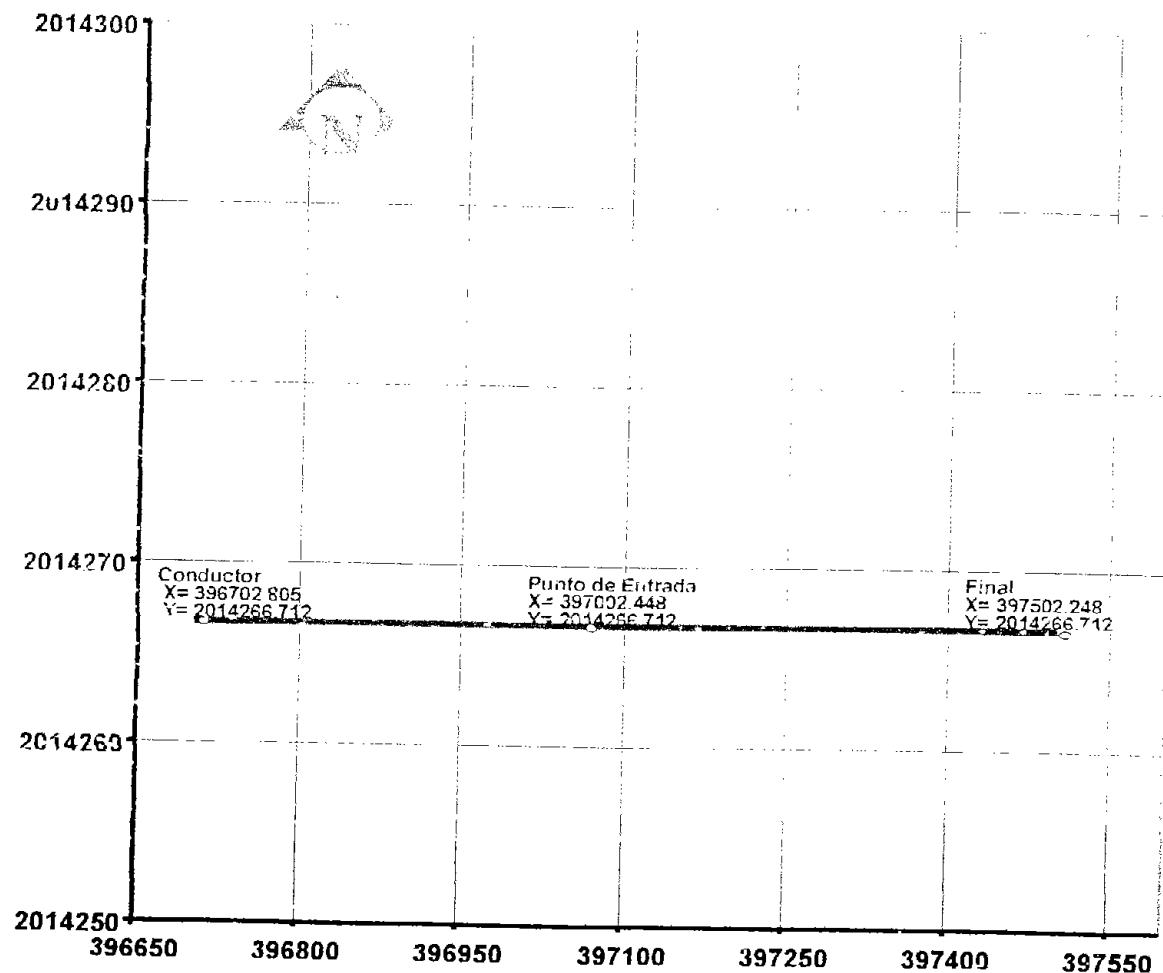

FIGURA III.4
Desplazamiento Horizontal

En la figura III.5 muestra la sección vertical del pozo.

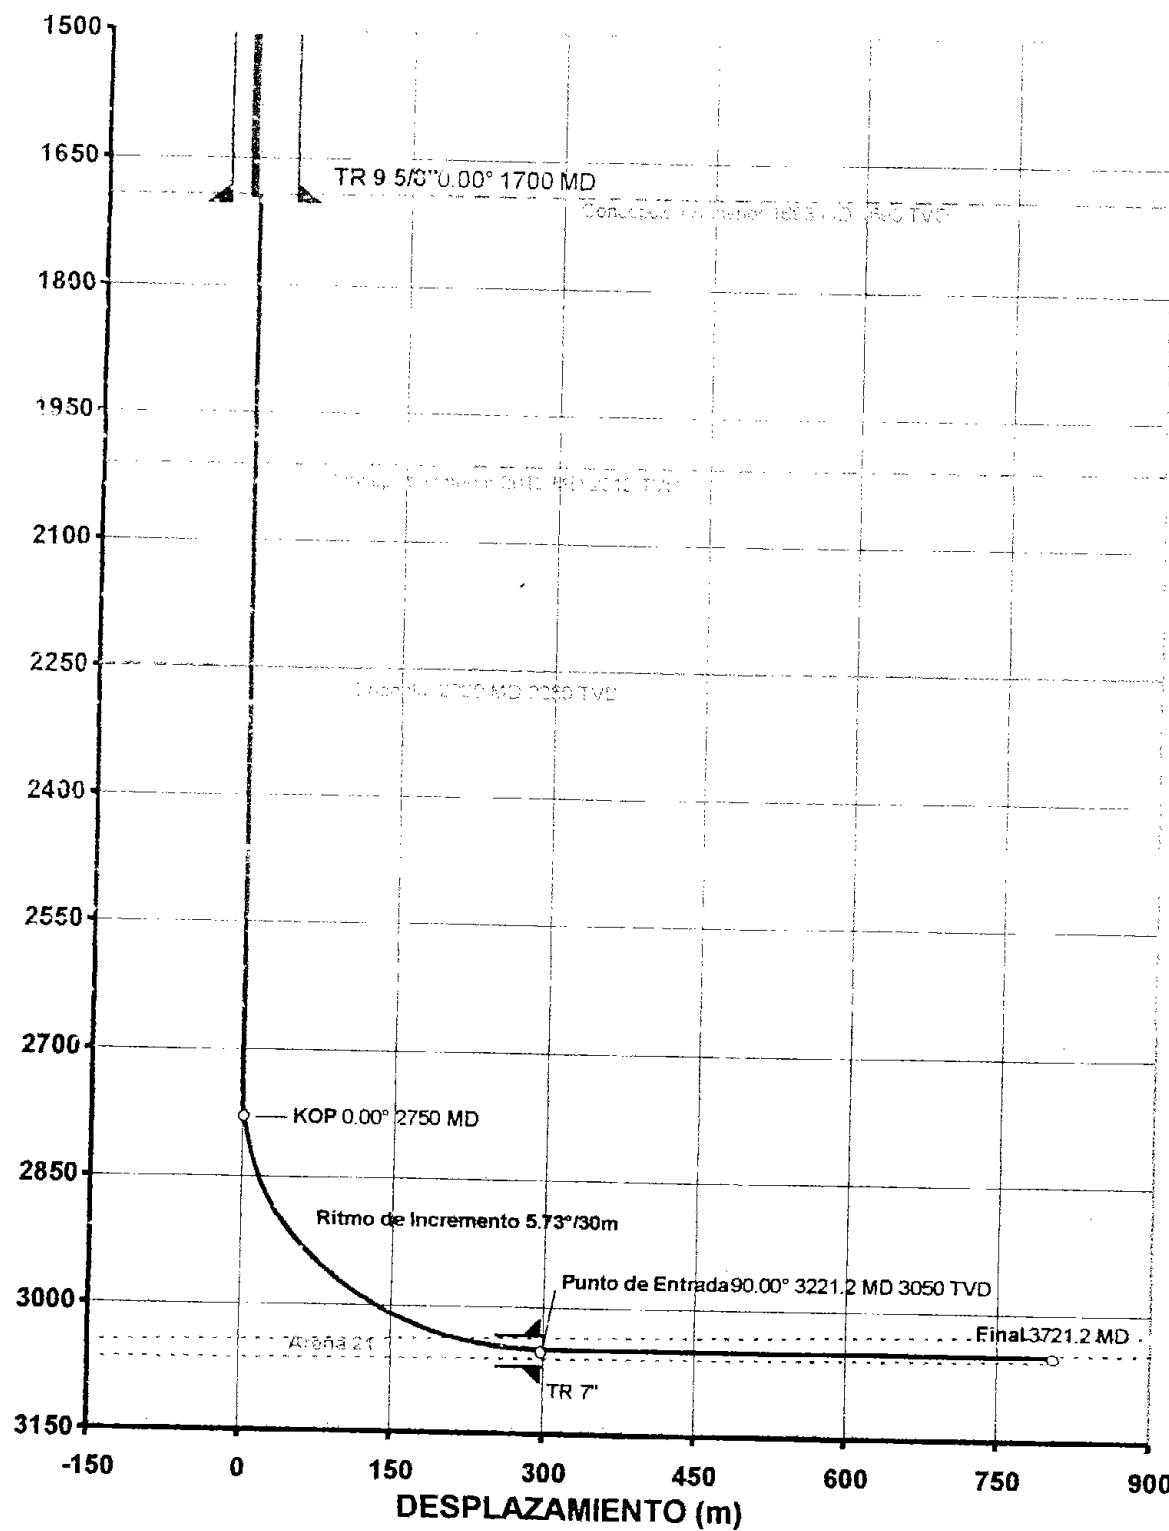

FIGURA III.5
Sección Vertical

Programa de Perforación Direccional.

En esta sección se propone un programa de perforación direccional.

Las etapas de perforación vertical se utilizaran sartas convencionales. Una vez perforada la etapa de 12 1/4" y cementar la TR de 9 5/8" a 1700m, se propone el siguiente programa:

1. Perforar con barrena de 8 1/2", verticalmente hasta 2750m, donde se iniciara a desviar, circular y sacar la tubería para cambiar sarta convencional por sarta direccional.

2. **Etapa de construcción de curva** .Armar y bajar barrena de 8 1/2" para desviar el pozo con un incremento angular de 5.73°/30m en dirección N 90 E hasta alcanzar 90° de inclinación a la profundidad de 3221.2 m (3050 PV). La distribución de sarta será la siguiente:

- ✓ Barrena 8 1/2"
- ✓ Motor de Fondo (herramienta de navegación Tridimensional).
- ✓ Estabilizador 6 3/4".
- ✓ Drill Collar corto 6 3/4".
- ✓ Sub de Comunicación 5".
- ✓ MWD 6 3/4".
- ✓ Sub 6 3/4".
- ✓ LWD-CDR 6 3/4".
- ✓ TP 5", 19.5 lb/pie, X-95.
- ✓ HW 5".
- ✓ Martillo 6 3/4".
- ✓ HW 5".
- ✓ TP 5", 19.5 lb/pie, S-135.

Parámetros de perforación:

- Peso sobre barrena de 6-8 ton.
- Gasto de 400-420 G.P.M.
- Revoluciones de 120-150 R.P.M.

Fluido de control será de emulsión inversa de 1.30 gr/cm³.

Este aparejo de fondo con herramienta LWD-CDR proporciona; resistividad tipo inducción y rayos Gamma.

Con la información a tiempo real se tiene la capacidad de poder correlacionar con pozos existentes y definir adecuadamente el asentamiento de la TR de 7".

Circular y sacar la sarta y posteriormente bajar la TR de 7" y cementarla.

3. Armar y bajar barrena de 5 7/8" para cortar cemento, zapata y formación hasta la profundidad de 3224 m, 3 metros por debajo de la zapata de 7". La distribución de sarta será la siguiente:

- ✓ Barrena 5 7/8".
- ✓ Estabilizador 4 3/4".
- ✓ Drill Collar normal 4 3/4".
- ✓ Estabilizador 4 3/4"
- ✓ TP 3 1/2", 15.5 lb/pie, X-95.
- ✓ HW 3 1/2".
- ✓ Martillo 4 3/4".
- ✓ HW 3 1/2".
- ✓ TP 3 1/2", 15.5 lb/pie, S-135.

Parámetros de perforación:

- Peso sobre barrena de 3-5 ton.
- Gasto de 200 G.P.M.
- Revoluciones de 60-80 R.P.M.

4. **Etapa horizontal.** Armar y bajar barrena de 5 7/8" para perforar hasta la profundidad medida de 3721.2 m, navegando horizontalmente con herramienta LWD en tiempo real para mantenerse dentro de la Arena 21. Al terminar de perforar circular y sacar aparejo. La distribución de sarta será la siguiente:

Barrena 5 7/8".

- ✓ Motor de fondo 4 3/4".
- ✓ Estabilizador 4 3/4".

- ✓ MWD 4 3/4".
- ✓ LWD 4 3/4"
- ✓ TP 3 1/2", 15.5 lb/pie, X-135.
- ✓ HW 3 1/2".
- ✓ Martillo 4 3/4".
- ✓ HW 3 1/2".
- ✓ TP 3 1/2", 15.5 lb/pie, S-135.

Parámetros de perforación:

- Peso sobre barrena de 5-8 ton.
- Gasto de 200-250 G.P.M.
- Revoluciones de 60-70 RPM en superficie (Más R.P.M. del motor de fondo)

Fluido de control de emulsión inversa de 1.30 gr/cm³.

5.- Bajar tubería corta de explotación de 5", 18 lb/pie, P-110, a 3721.2 m y dejarla colgada con un empacador permanente para TR 7" a 3200 m, la tubería esta ranurada de 3721.2 a 3221.2 (500 m), con esto se concluye la etapa de perforación.

Aparejos de Perforación Direccional.

En la figura III.6 y la Tabla 3.3 se describe el aparejo para la etapa direccional de 8 1/2".

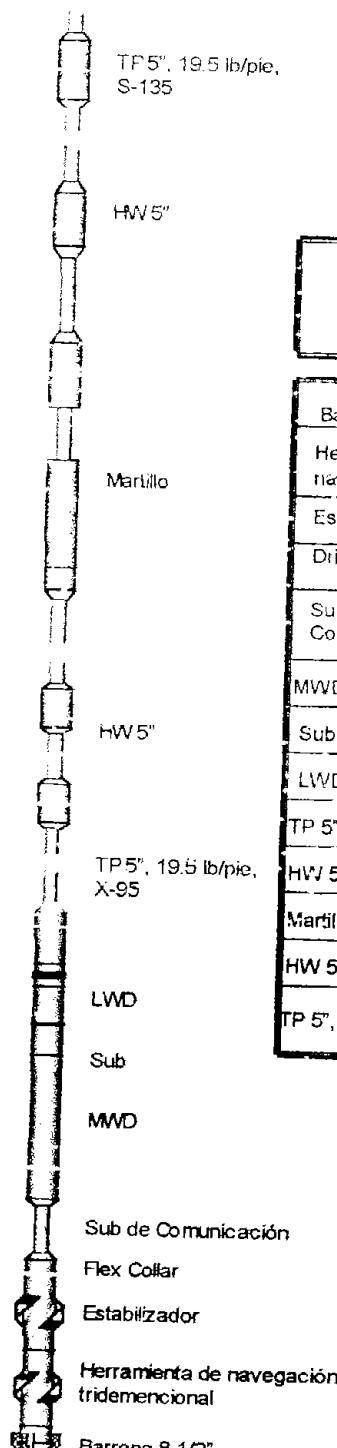

Tabla 3.3

FIGURA III.7
Aparejo de $5\frac{7}{8}$ "

En la figura III.8 y la Tabla 3.5 se describe el aparejo de 5 7/8" de la etapa horizontal de 3221.2 a 3721.2 m.

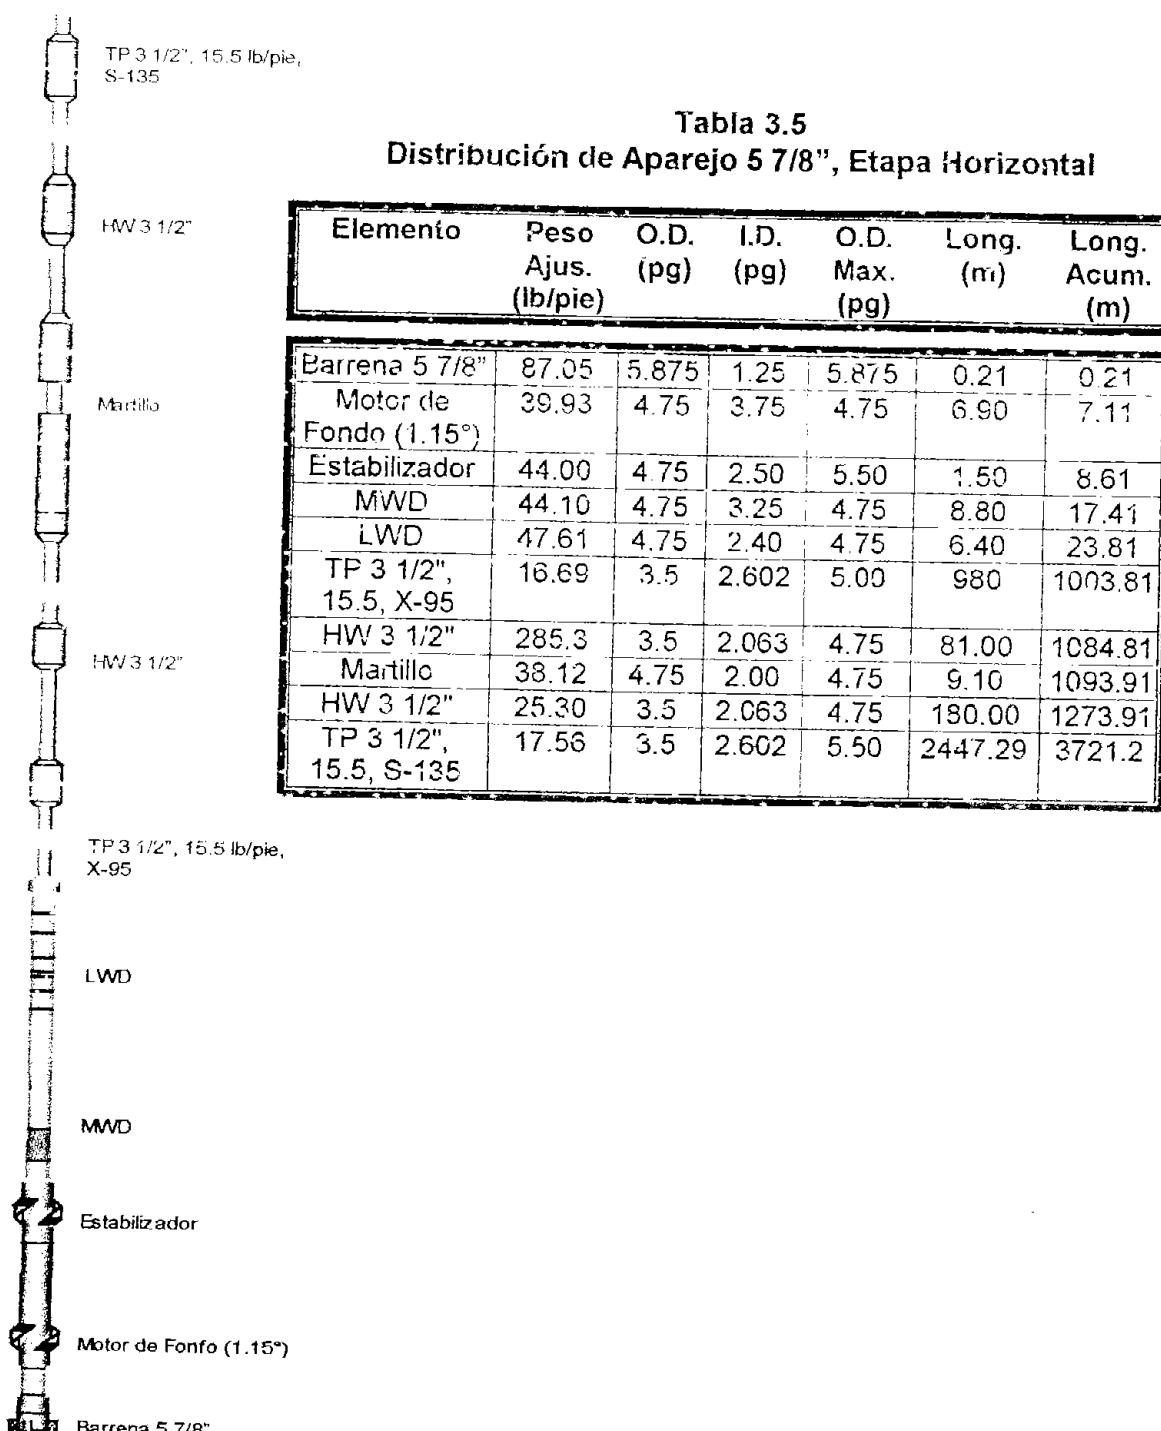

FIGURA III.8
Aparejo de 5 7/8", Etapa Horizontal

Analisis de Torque y Arrastre.

La mayor preocupación en la planificación del diseño de un pozo direccional u horizontal es la transmisión efectiva del peso de la sarta y de la rotación de la sarta de fondo. La fricción es una función del torque y arrastre. El torque es la componente rotacional de la fuerza de contacto entre la sarta y las paredes del pozo y son importantes cuando se esta perforando. El arrastre es la componente axial y son importantes durante los viajes.

Con el fin de analizar el torque y arrastre, se utilizará el programa Drag 8, con el cual se calcularán las fricciones a lo largo de las diferentes sartas durante la perforación, repasos y viajes. Los resultados se compararán a los límites mecánicos de los componentes de las sartas de perforación.

Etapa 8 ½", Construcción de la curva.

El análisis de torque y arrastre para esta sección se llevó a cabo con los siguientes datos:

1. Densidad de lodo de 1.30 gr/cm³.
2. Revoluciones por minuto de 130 RPM.
3. Velocidad de viaje 30 fi/min.
4. Peso sobre barrena de 8 ton.
5. Factor de fricción en la TR de 9 5/8" de 0.2.
6. Factor de fricción en agujero abierto de 0.3.
7. El punto neutro se localiza a 2548.44 m de la superficie.

En la figura III.9 se muestra el análisis de la carga en diferentes operaciones.

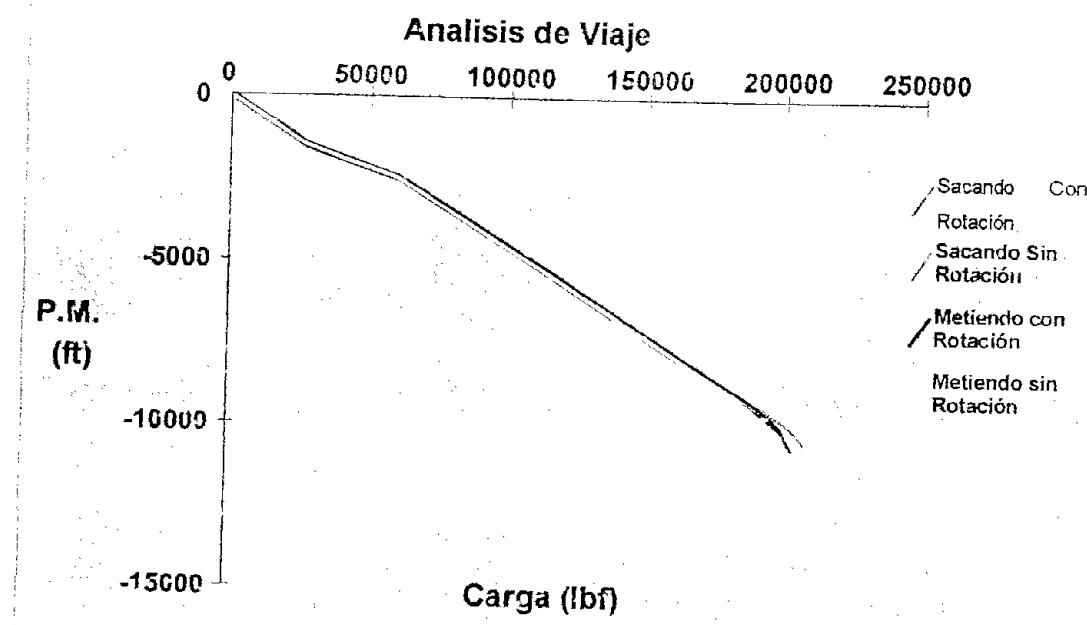

FIGURA III.9
Distribución de Carga

En la figura III.10 se presenta la grafica del torque cuando la tubería esta en movimiento.

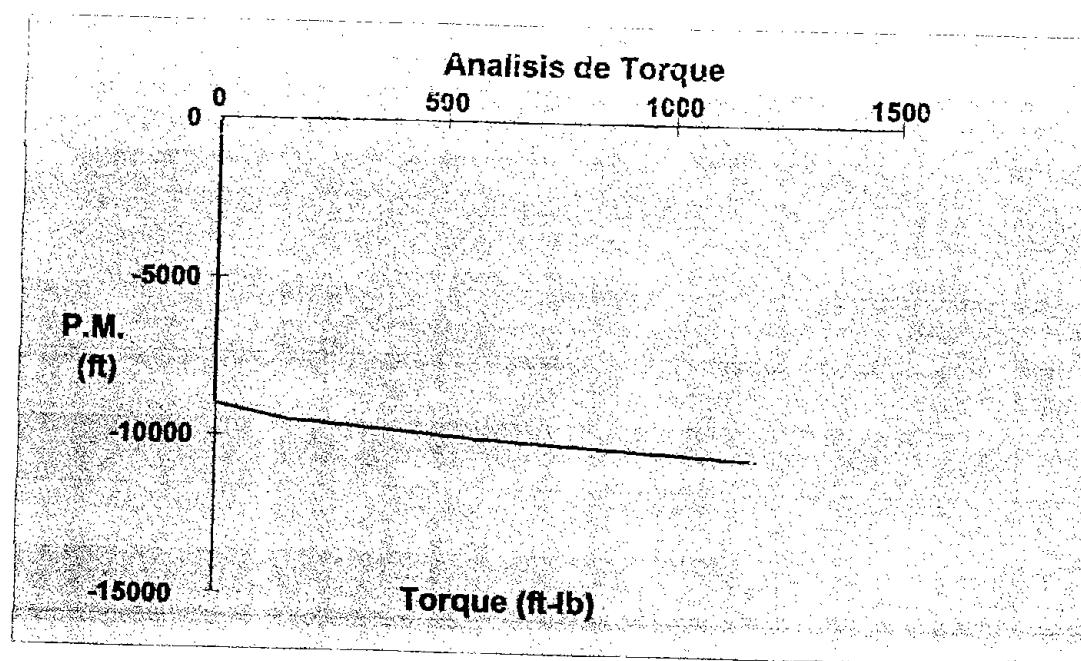

FIGURA III.10
Torque con Tubería en Movimiento

En la figura III.11 se presenta la distribución del torque cuando la sarta esta en el fondo estática con rotación y se presenta los límites de torque para cada componente de la sarta y al figura III.12 muestra la carga axial sacando tubería.

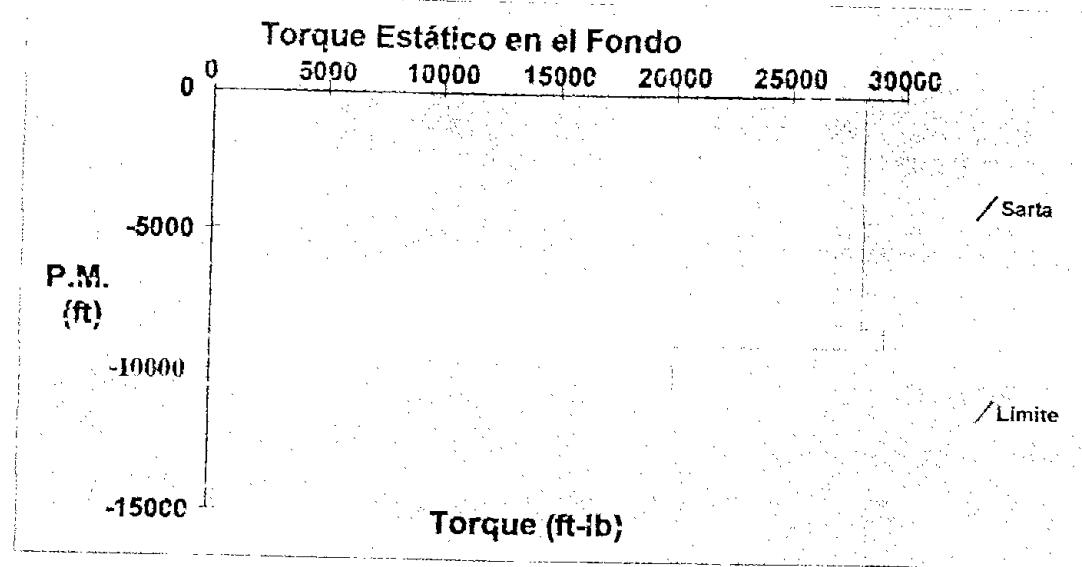

FIGURA III.11
Torque de la sarta con rotación en el fondo

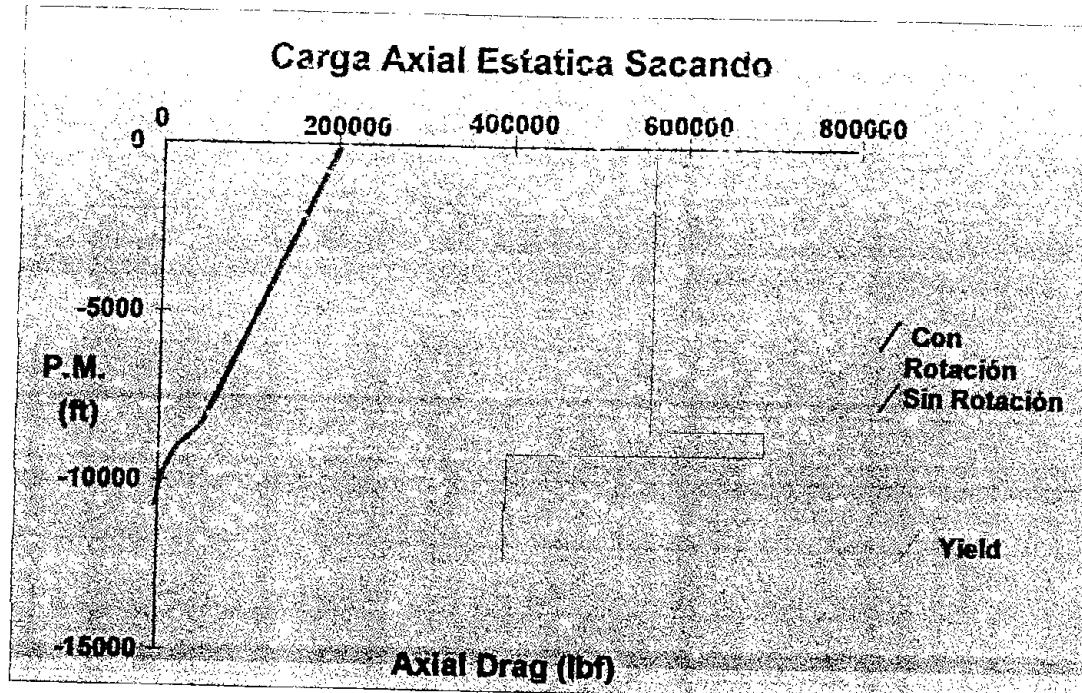

FIGURA III.12
Carga Axial, Sacando Tubería

En la figura III.13 se presenta el arrastre metiendo tubería y los límites de pandeo.

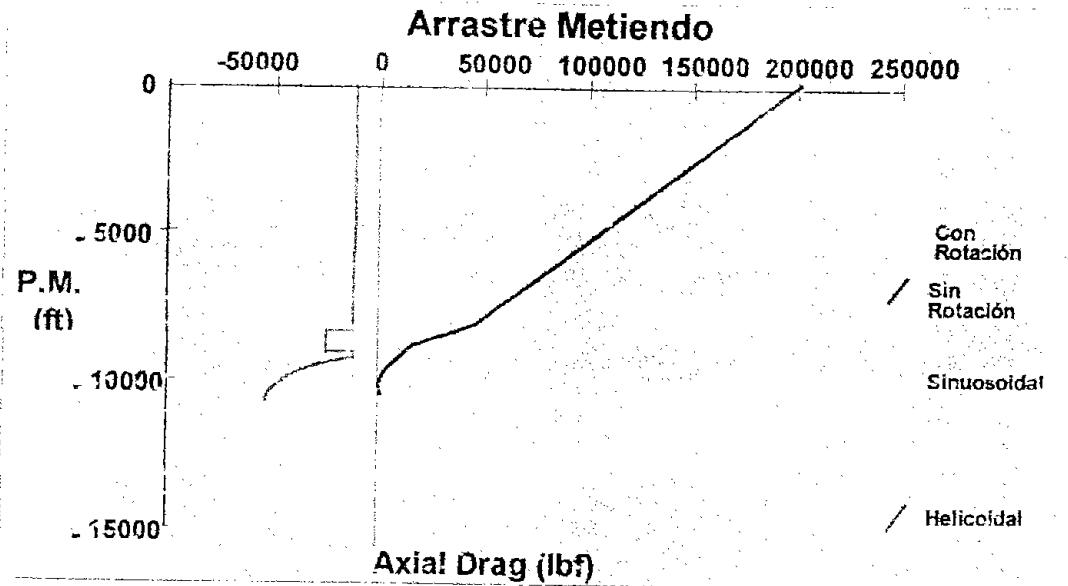

FIGURA III.13
Arrastre metiendo Tubería

En la figura III.14 se presenta la distribución de carga axial cuando se está perforando.

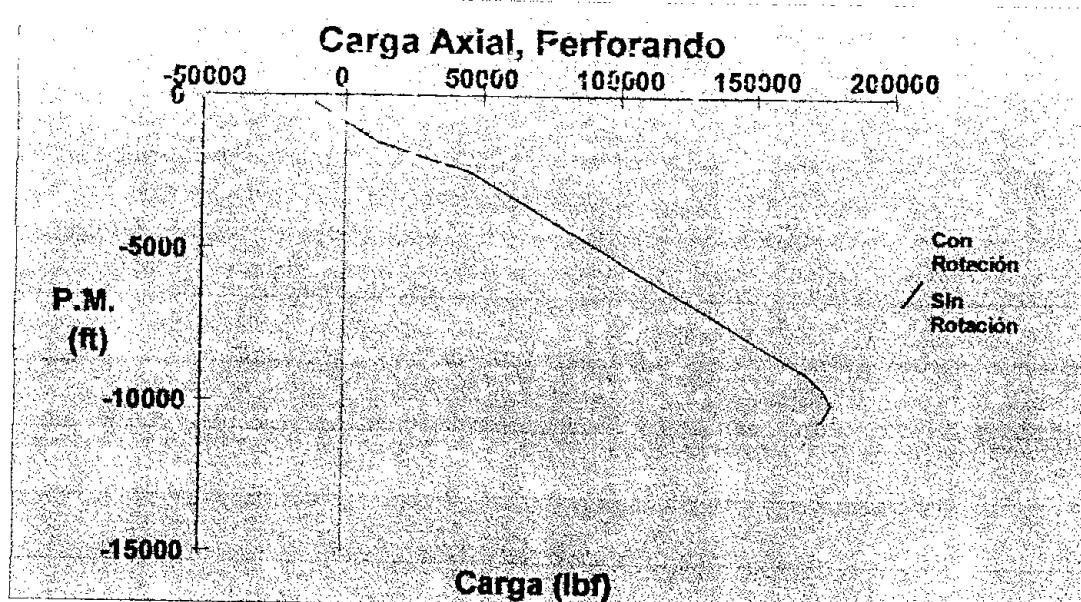

FIGURA III.14
Carga Axial, Perforando.

La figura III.15 muestra la distribución del torque al estar perforando, y la figura III.16 muestra el torque y los límites de cada componente de la sarta.

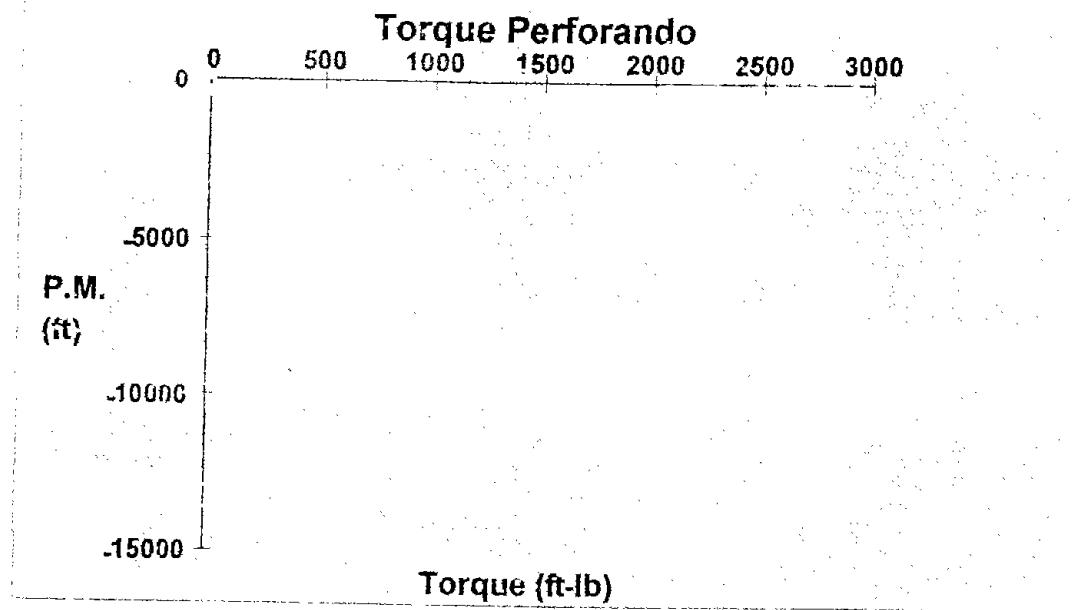

FIGURA III.15
Torque al estar Perforando

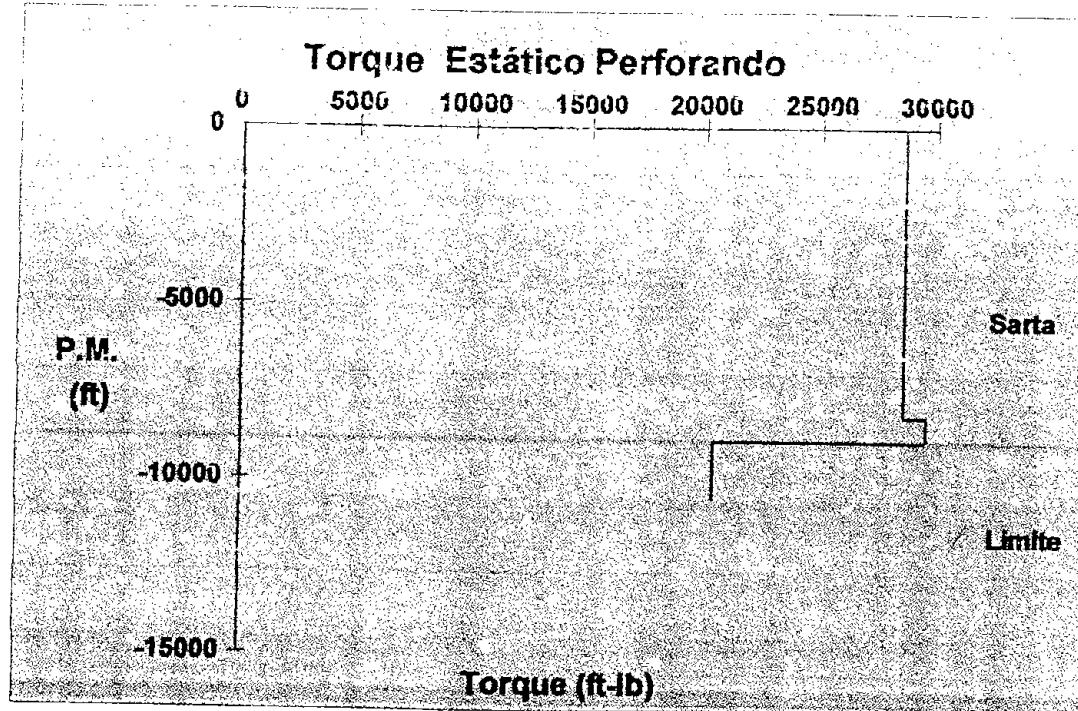

FIGURA III.16
Torque con tubería en el fondo

En la figura III.17 se muestra el arrastre, y los límites de pandeo.

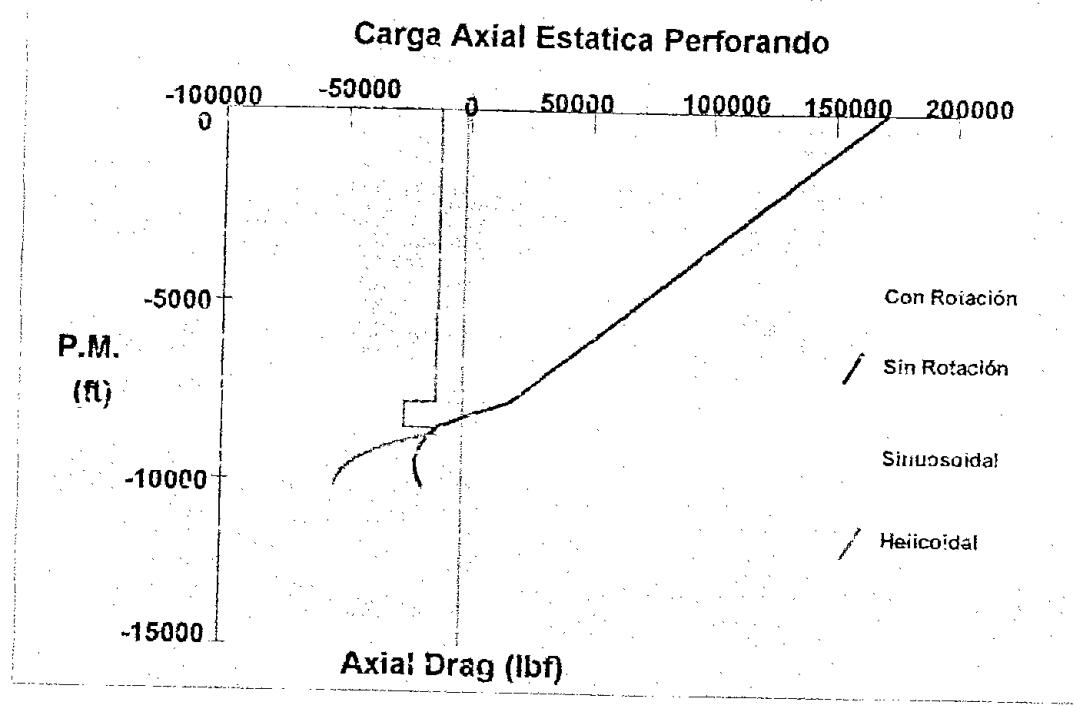

FIGURA III.17
Arrastre, Perforando

Como se observa en la anterior figura, al estar perforando sin rotación y con 8 ton. De peso sobre la barrena la tubería estará sometida a compresión y se inicia a presentarse el pandeo helicoidal en la zona de la tubería pesada (HW). En la figura III.18 se presenta la comparación con 4 ton de peso sobre barrena para el caso de perforar sin rotación.

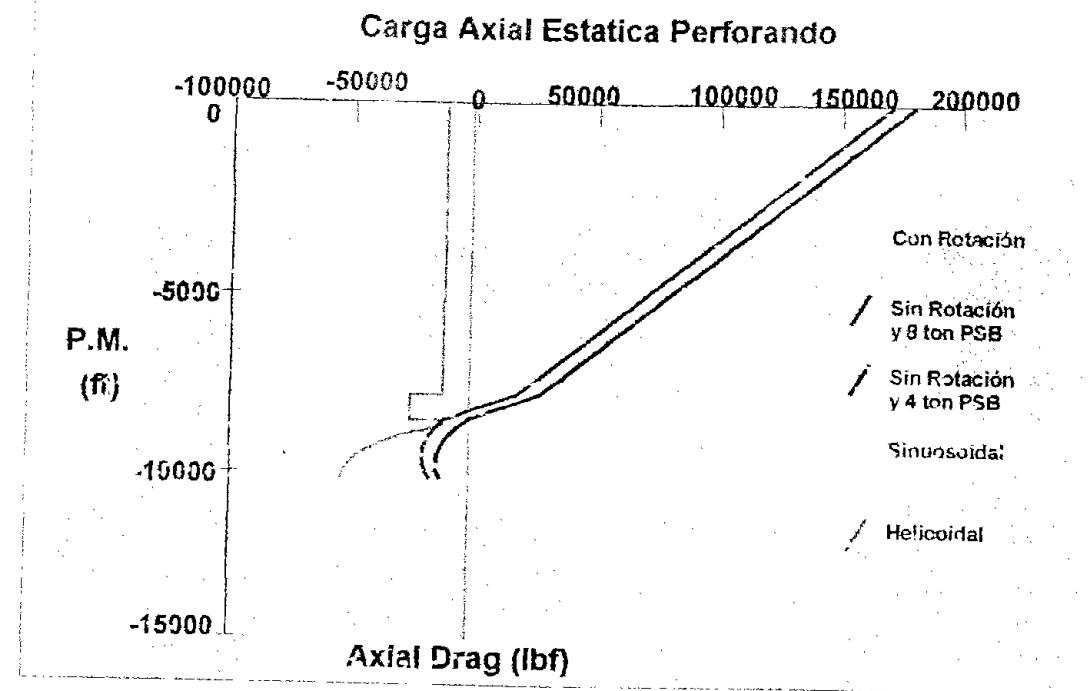

FIGURA III.18
Arrastre, Perforando con
distintos PSB

En la figura III.8 se observa que para evitar el pandeo se puede perforar sin rotación con 4 ton de PSB como máximo.

Etapa 5 7/8" Perforación Horizontal.

El análisis de torque y arrastre para esta sección se llevó a cabo con los siguientes datos:

1. Densidad de lodo de 1.30 gr/cm³.
2. Revoluciones por minuto de 130 RPM.
3. Velocidad de viaje 30 ft/min.
4. Peso sobre barrena de 8 ton.
5. Factor de fricción en la TR de 7" de 0.25.
6. Factor de fricción en agujero abierto de 0.35
7. El punto neutro se localiza a 2541.2944 m de la superficie.

En la figura III.19 se muestra el análisis de la carga en diferentes operaciones.

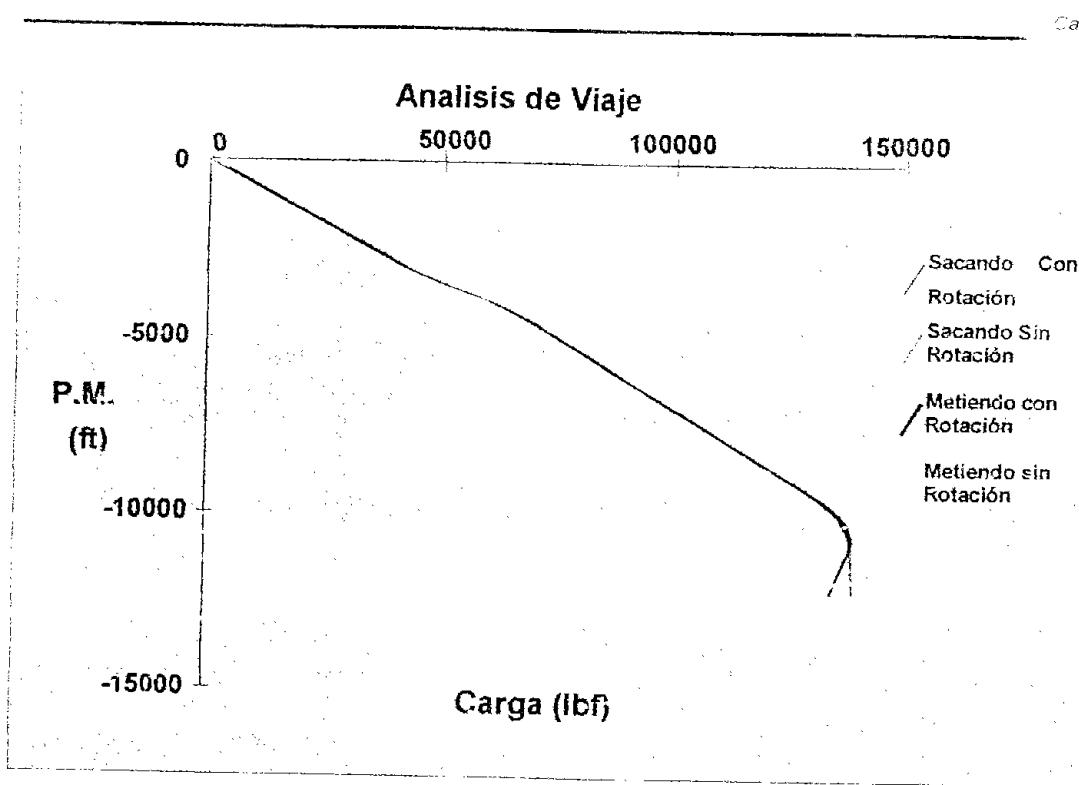

FIGURA III.19
Distribución de Cargas

En la figura III.20 se presenta la grafica del torque cuando la tubería esta en movimiento.

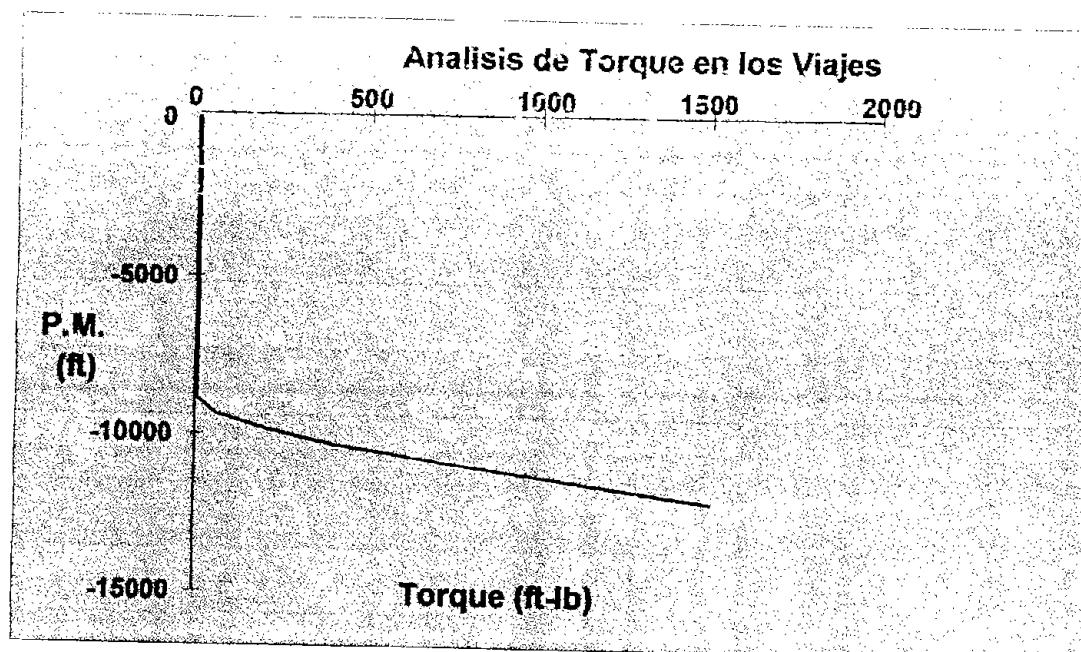

FIGURA III.20
Torque con Tubería en Movimiento

En la figura III.21 se presenta la distribución del torque cuando la sarta esta en el fondo estática con rotación y se presenta los límites de torque para cada componente de la sarta y al figura III.22 muestra la carga axial sacando tubería.

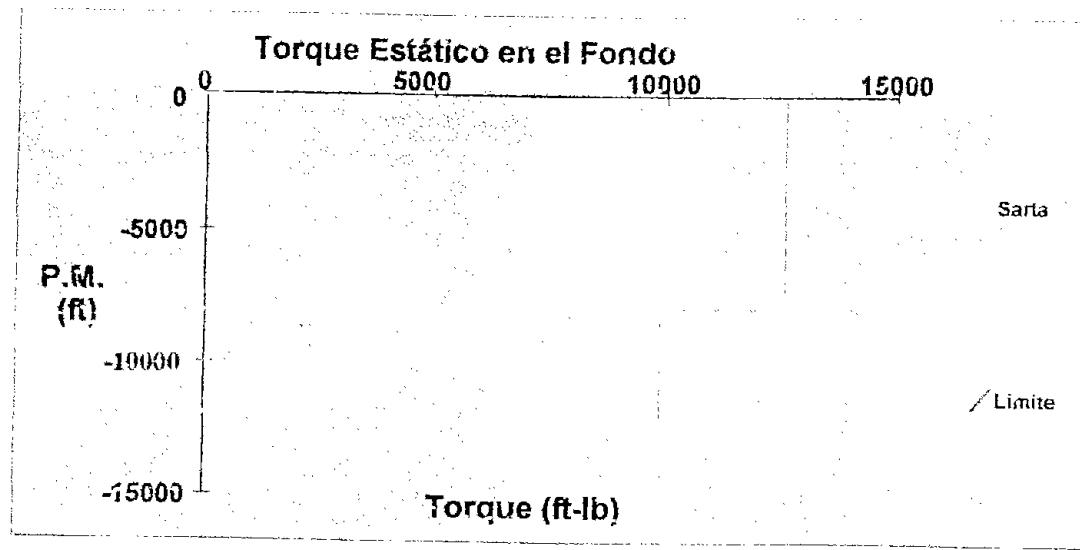

FIGURA III.21
Torque de la sarta con rotación en el fondo

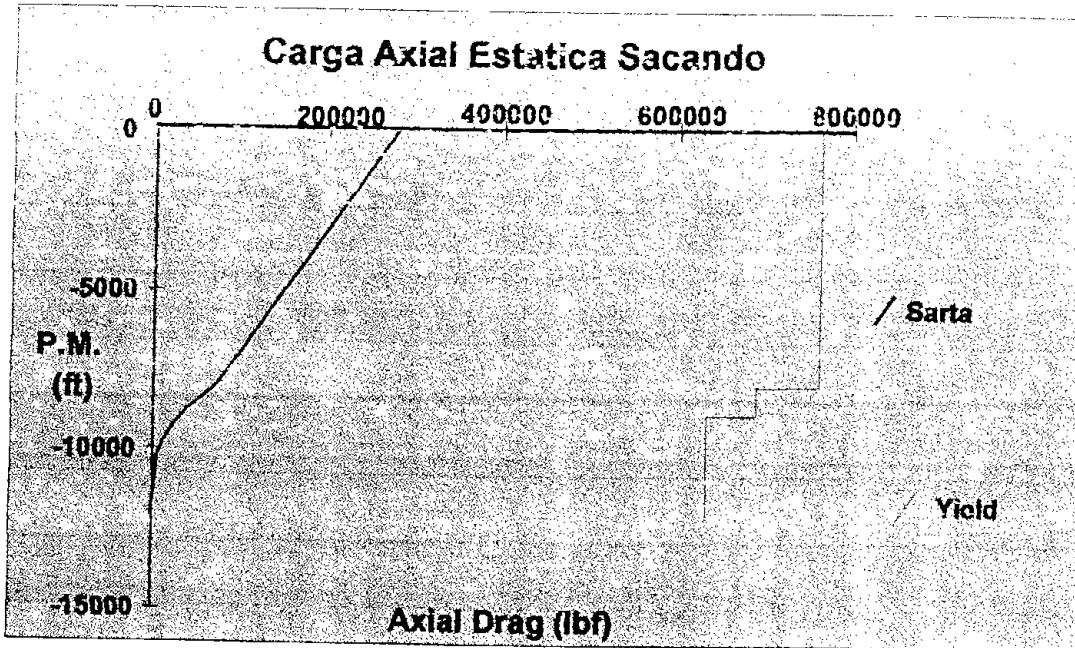

FIGURA III.22
Carga Axial, Sacando Tubería

En la figura III.23 se presenta el arrastre metiendo tubería y los límites de pandeo.

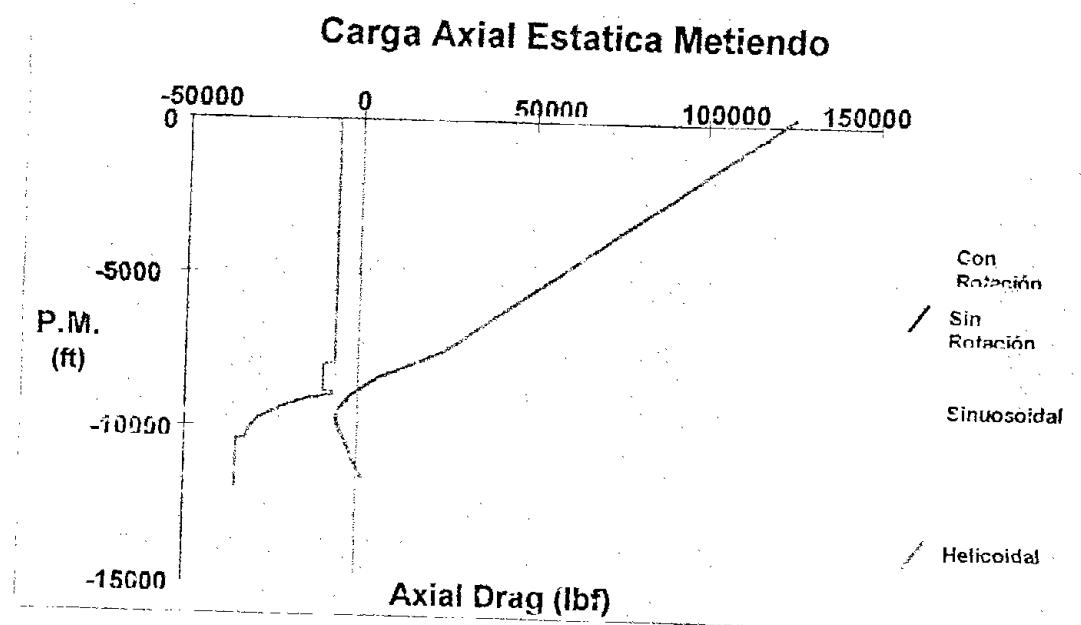

FIGURA III.23
Arrastre metiendo Tubería

En la figura III.24 se presenta la distribución de carga axial cuando se está perforando.

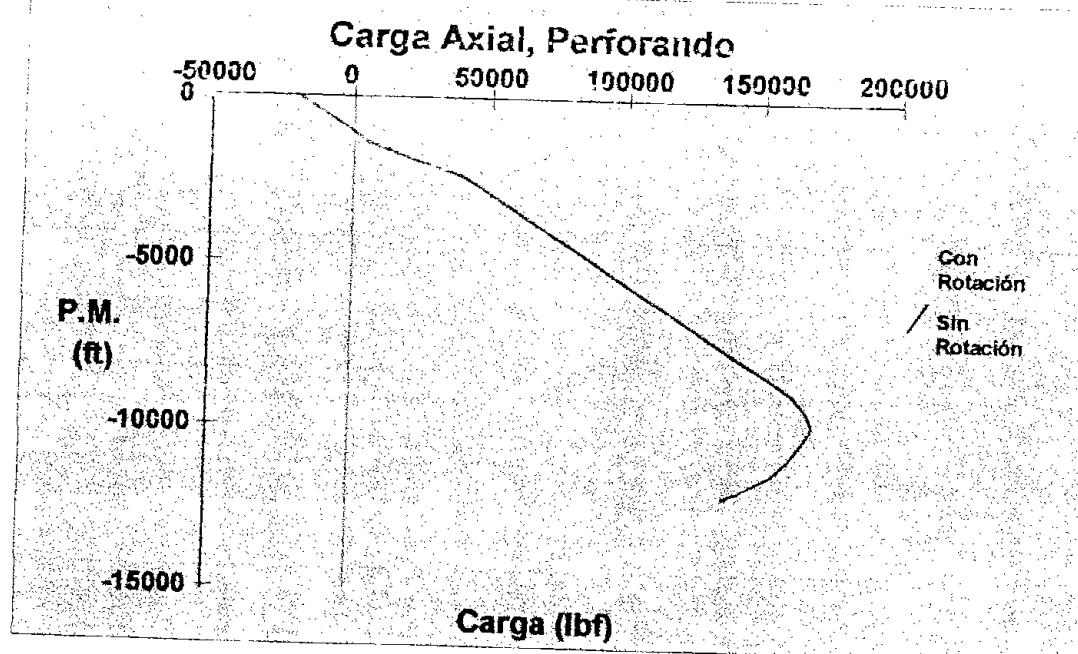

FIGURA III.24
Carga Axial, Perforando.

La figura III.25 muestra la distribución del torque al estar perforando, y la figura III.26 muestra el torque y los límites de cada componente de la sarta.

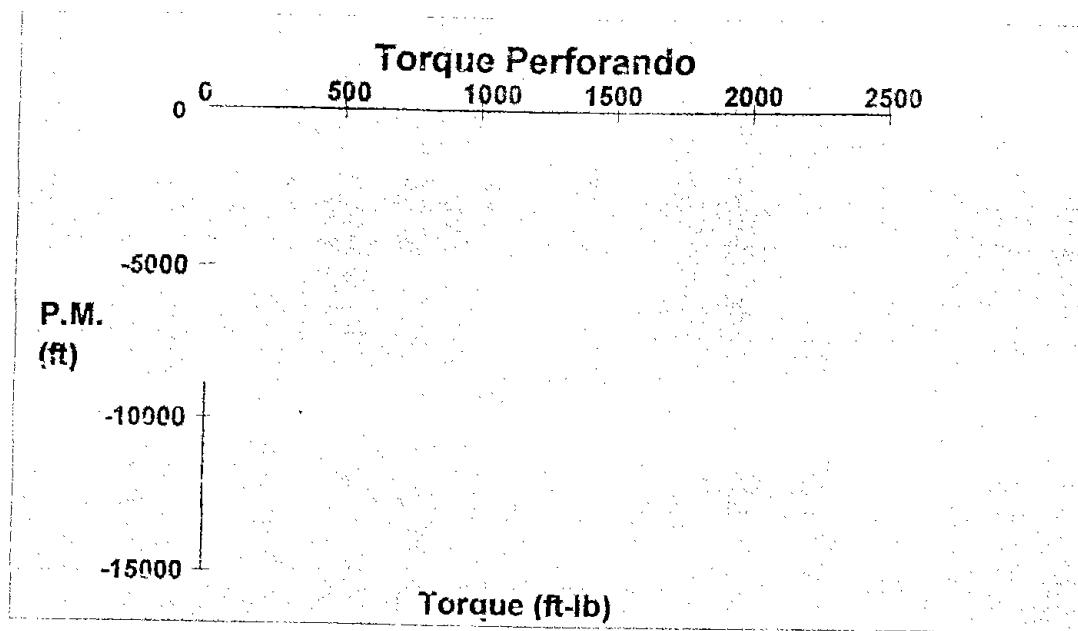

FIGURA III.25
Torque al estar Perforando

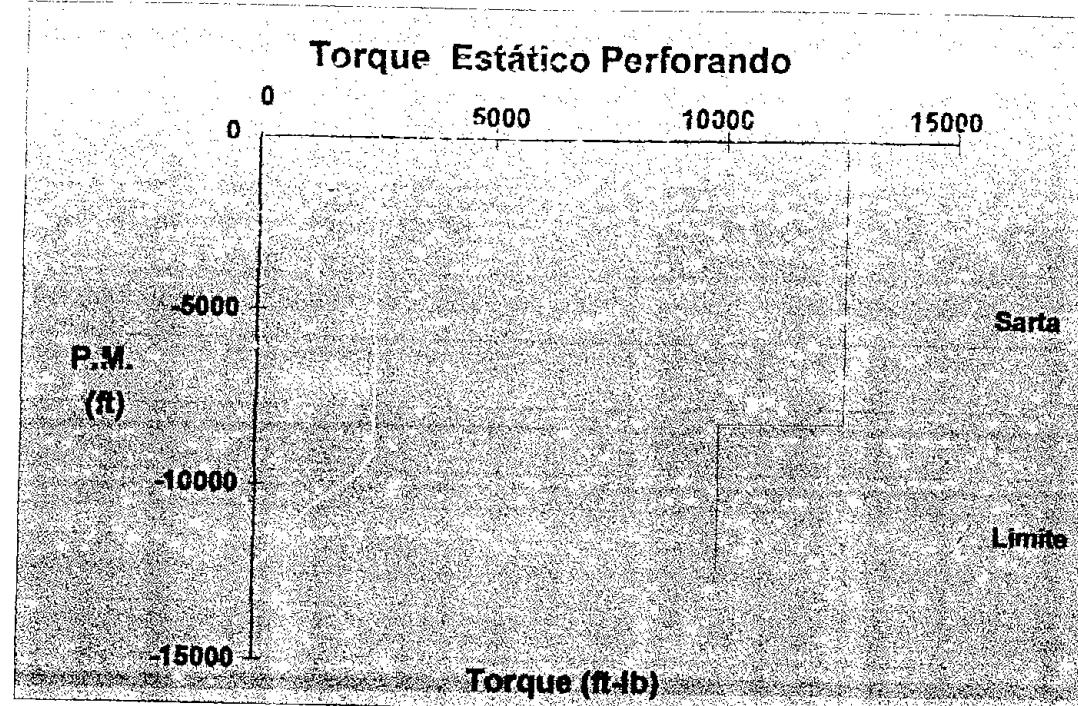

FIGURA III.26
Torque con tubería en el fondo

En la figura III.27 se muestra el arrastre, y los límites de pandeo .

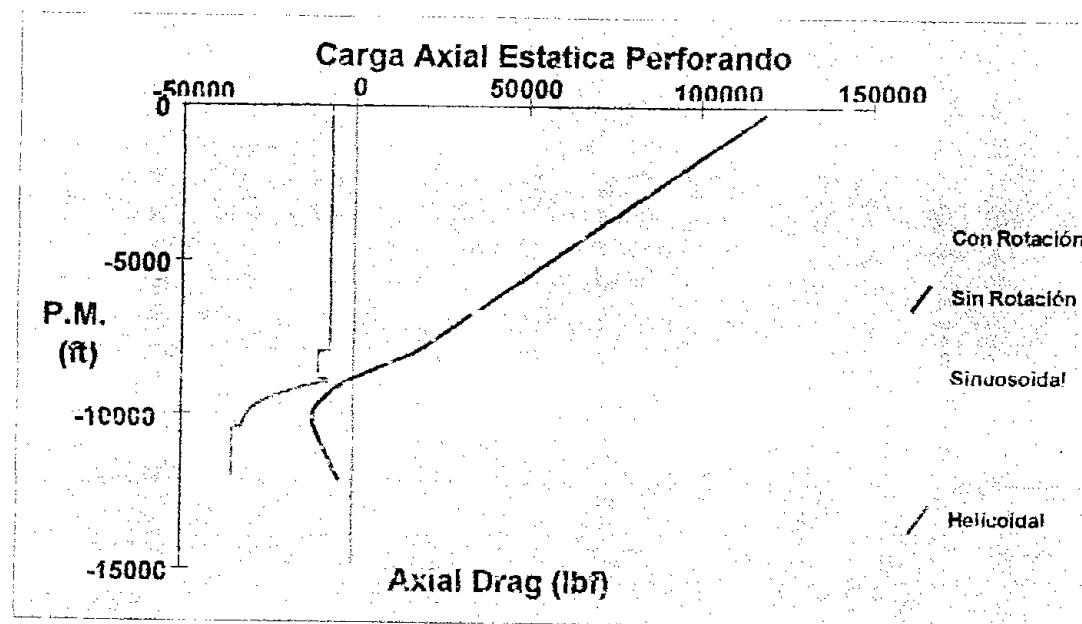

FIGURA III.27
Arrastre, Perforando

Como se observa en la anterior figura, al estar perforando sin rotación y con 8 ton. De peso sobre la barrena la tubería estará sometida a compresión y próximamente el pandeo helicoidal en la zona de la tubería pesada (HW). Por lo que se recomienda evitar la perforación sin rotación. En caso necesario se debe de realizar con menor peso sobre barrena para evitar el pandeo helicoidal.

Los cálculos de torque y arrastre se presentan en el anexo.

Hidráulica.

El fluido de perforación tiene como principal función después de controlar el pozo, la limpieza del fondo y el acarreo de los recortes hasta la superficie. La capacidad de remoción de los recortes por el fluido de perforación, se da en función de la presión a la salida de las toberas y del gasto de circulación. Estos parámetros se ligan con el concepto de potencia hidráulica.

Cuando la potencia hidráulica, producto de presión por gasto es la máxima, la capacidad de remoción de recortes será óptima.

La máxima potencia hidráulica en la barrena depende de la efectividad de la bomba, debido a que la velocidad de penetración aumenta; sin embargo una vez que se llega al nivel de limpieza perfecta (recortes que se levantan del fondo a medida que se generan), cualquier incremento en la potencia hidráulica deja de afectar a la velocidad de penetración.

El análisis de la hidráulica para el pozo en estudio se realizó mediante el uso de una hoja de cálculo. las características del fluido fueron proporcionados por ingenieros químicos de perforación del Activo los cuales consideran un fluido de emulsión inversa para perforar la etapa direccional y horizontal.

Hidráulica de la Etapa de 8 1/2".

En la tabla 3.6 se describen los parámetros y características del fluido de perforación a utilizar

**Tabla 3.6

CONCLUSIONES.

1. La perforación de los pozos horizontales ofrece ventajas importantes con respecto al incremento en la producción de los pozos, pero la corta experiencia que tenemos en nuestro país en la perforación horizontal, nos implica un mayor riesgo.
2. La interpretación del campo Rodador y la gran cantidad de información técnica disponible nos permite considerar que es un buen campo candidato para la aplicación de la perforación horizontal.
3. Es importante que se desarrolle el proyecto de perforación de cuatro pozos horizontales, porque ayudará al dominio de la técnica y la construcción de la curva de aprendizaje.
4. A medida que se simulen las diferentes actividades de la perforación tales como: torque y arrastre, permitirá identificar los puntos críticos durante la perforación de los pozos.

| III.20 | Torque con tubería 5 7/8" en movimiento | 49 |
| III.21 | Torque, rotando sarta en el fondo | 50 |
| III.22 | Carga Axial, sacando tubería 5 7/8" | 50 |
| III.23 | Arrastre, metiendo tubería 5 7/8" | 51 |
| III.24 | Carga Axial perforando, 5 7/8" | 51 |
| III.25 | Torque, perforando con 5 7/8" | 52 |
| III.26 | Torque con tubería en el fondo | 52 |
| III.27 | Arrastre perforando con 5 7/8" | 53 |

INDICE DE TABLAS

| No. de Tabla | Titulo | Página |
|--------------|---|--------|
| 2.1 | Áreas con posibilidades | 20 |
| 2.2 | Reservas del campo Rodador | 26 |
| 3.1 | Distribución de TR's | 31 |
| 3.2 | Trayectoria del Pozo | 32 |
| 3.3 | Aparejo de 8 1/2" | 39 |
| 3.4 | Aparejo de 5 7/8" | 40 |
| 3.5 | Aparejo de 5/8", etapa horizontal | 41 |
| 3.6 | Condiciones de hidráulica, etapa 8 1/2" | 54 |
| 3.7 | Calculo de caídas de presión, etapa 8 1/2" | 55 |
| 3.8 | Optimización de la hidráulica | 56 |
| 3.9 | Condiciones de hidráulica, etapa 5 7/8" | 56 |
| 3.10 | Calculo de caídas de presión etapa 5 7/8" | 57 |
| 3.11 | Optimización de la hidráulica, etapa 5 7/8" | 58 |

Anexo

ANEXO

Etapa Construcción de Curva 8.5"

Distribución de Cargas y Torque Sacando con Rotación

| Bit Locate @10567.6(ft) | Measured Depth | Inclin. Angle | Dogleg Severity (D/100ft) | Normal Force (lb/ft) | Axial Drag (lbf) | Torque (ft-lb) | Drag Limit (lbf) | Torque Limit (ft-lb) |
